(Received 26 January 2009; published 12 March 2009)

We numerically study free expansion of a few Lieb-Liniger bosons, which are initially in the ground state of an infinitely deep hard-wall trap. Numerical calculation is carried out by employing a standard Fourier transform, as follows from the Fermi-Bose transformation for a time-dependent Lieb-Liniger gas. We study the evolution of the momentum distribution, the real-space single-particle density, and the occupancies of natural orbitals. Our numerical calculation allows us to explore the behavior of these observables in the transient regime of the expansion, where they are nontrivially affected by the particle interactions. We derive analytically (by using the stationary phase approximation) the formula which connects the asymptotic shape of the momentum distribution and the initial state. For sufficiently large times, the momentum distribution coincides (up to a simple scaling transformation) with the shape of the real-space single-particle density (the expansion is asymptotically ballistic). Our analytical and numerical results are in good agreement.

I. INTRODUCTION

Exactly solvable models describing interacting bosons in one dimension (1D) have been studied over decades since the pioneering work of Girardeau [1] and Lieb and Liniger (LL) [2]. The interest in these models is greatly stimulated with recent experiments [3–5], in which ultracold atomic gases are tightly confined in 1D atomic waveguides such that transverse excitations are suppressed. The LL model describes 1D bosons with pointlike contact interactions of a given strength c [2]. In the limit of sufficiently strong interactions, the LL gas enters the Tonks-Girardeau (TG) regime of impenetrable bosons [1]; the TG regime can be obtained at very low temperatures, with strong effective interactions, and low linear particle densities [6–8]. An interesting aspect of 1D Bose gases, which can be probed experimentally from weakly to the strongly interacting regime, is their behavior out of equilibrium (e.g., see Ref. [5]). An exact (analytical or numerical) theoretical calculation of nonequilibrium dynamics of a LL gas is a complex many-body problem, which was studied in a few cases [9–13]. A paradigmatic problem in this context is one-dimensional free expansion from an initially localized state [12–18]. Quite generally, free expansion can be used to provide information on the initial state (e.g., see Refs. [19–21] and references therein).

Free expansion of a LL gas was studied in Ref. [14] by using the hydrodynamic approximation [8]; it was demonstrated that the evolution of single-particle (SP) density is not self-similar for finite interaction strength c . Exact solutions of free expansion were studied both in the TG regime ($c=\infty$) [15–18] and for a repulsive LL gas ($0\leq c<\infty$) [12,13]. In the TG regime, it has been shown that the momentum distribution approaches that of noninteracting fermions during free expansion [15,16]. This was shown numerically by using the model of hard-core bosons on the lattice in Ref. [15] and by using the stationary phase approximation in the continuous TG model (for the initial harmonic confine-

ment) in Ref. [16]. For quite general initial conditions, the asymptotic form of the wave functions for a freely expanding LL gas was calculated in Ref. [13] by using the stationary phase approximation (free expansion for a particular family of initial conditions was previously considered in [12]). It was shown that these asymptotic wave functions vanish at the hyperplanes of contact between particles, which is characteristic for TG wave functions [1]. However, it was emphasized that the properties of such asymptotic states can considerably differ from the physical properties of a Tonks-Girardeau gas in the ground state of some trapping potential [13] (see also the second item in Ref. [12]). We also point out that expansion dynamics is the subject of studies in other 1D models; for example, particles interacting via an inverse-square pair potential [22], strongly correlated fermions [23], and strongly interacting Bose-Fermi mixtures [24]. To the best of our knowledge, studies of the momentum distribution of an expanding LL gas, which are based on exact time-dependent solutions, have not yet been made.

Here we numerically study free expansion of a few Lieb-Liniger bosons, which are initially in the ground state of an infinitely deep hard-wall trap. The numerical calculation is carried out by employing a standard Fourier transform, as follows from the Fermi-Bose transformation for a time-dependent Lieb-Liniger gas [9,12]. We focus on the dynamics of one-body observables of the system, in particular, the momentum distribution, the occupancies of natural orbitals, and also the real-space single-particle density. Our numerical calculation allows us to explore the behavior of these observables in the transient regime of the expansion, where they are nontrivially affected by the particle interactions. We derive analytically (by using the stationary phase approximation) the formula which connects the asymptotic shape of the momentum distribution and the initial state. For sufficiently large times, the momentum distribution coincides (up to a simple scaling transformation) with the shape of the real-space single-particle density, reflecting the fact that the expansion is asymptotically ballistic. The relation between the asymptotic expansion velocity of the LL cloud and the overall energy stored in the system is derived. Our analytical and numerical results are in good agreement.

*buljan@phy.hr

Before proceeding, let us devote a few words to some of the techniques for solving LL and TG models. The Bethe ansatz can be used to find the eigenstates for LL particles on an infinite line [2], with periodic boundary conditions [2], and in an infinitely deep box [25]. In the TG limit, both stationary [1] and time-dependent [26] wave functions, in an arbitrary external potential, are constructed by using the Fermi-Bose mapping, i.e., by solving the Schrödinger equation for spinless noninteracting fermions, after which the fermionic wave function is properly symmetrized to describe TG bosons [1,26]. In a similar fashion, exact time-dependent LL wave functions, in the absence of an external potential and on an infinite line, can be constructed by employing the Fermi-Bose mapping operator [9,12], which ensures that the so-called cusp condition (see, e.g., [10,12]) imposed by the interactions is obeyed during time evolution. In the light of the recent experiments [3–5], there has been renewed interest in exact studies of LL gases (stationary [27–32] and time dependent [10,12,13]) and time-dependent TG gases [15–18,26,33–37].

Even once a wave function describing a LL gas is known, determination of its correlation functions and observables such as the momentum distribution is difficult [38–45]. Various methods were developed over the years including the quantum inverse scattering method [38,45], $1/c$ expansions [39] from the TG ($c \rightarrow \infty$) regime, and quantum Monte Carlo integration [42]. In the TG limit, momentum distribution can be analytically studied in a few cases (e.g., see [46,47]). Numerical calculation of the TG momentum distribution can be performed also for excited and time-dependent states [15,37] (for hard-core bosons on the lattice, see [15]); a simple formula suitable for numerical calculations was recently derived for the continuous TG model [37] and generalized for 1D hard-core anyons [48].

II. LIEB-LINIGER MODEL AND OBSERVABLES OF INTEREST

We examine a system of N identical δ -interacting bosons which are constrained to one spatial dimension. The Schrödinger equation for that system, in the absence of any external potential, is

$$i \frac{\partial \psi_B}{\partial t} = - \sum_{i=1}^N \frac{\partial^2 \psi_B}{\partial x_i^2} + \sum_{1 \leq i < j \leq N} 2c \delta(x_i - x_j) \psi_B. \quad (1)$$

The strength of interaction is described by a parameter c (here we consider repulsive interactions $c > 0$). The initial condition $\psi_B(x_1, x_2, \dots, x_N, t=0)$ is a localized state, e.g., the LL ground state in some external trapping potential. Since we are dealing with symmetric (bosonic) wave functions, it is convenient to write Eq. (1) in one permutation sector of the configuration space, $R_1: x_1 < x_2 < \dots < x_N$,

$$i \frac{\partial \psi_B}{\partial t} = - \sum_{i=1}^N \frac{\partial^2 \psi_B}{\partial x_i^2}, \quad (2)$$

the δ -function interactions are equivalent to the boundary condition [2],

$$\left[1 - \frac{1}{c} \left(\frac{\partial}{\partial x_{j+1}} - \frac{\partial}{\partial x_j} \right) \right]_{x_{j+1}=x_j} \psi_B = 0. \quad (3)$$

It is worth mentioning that the so-called cusp condition in the TG limit (when $c \rightarrow \infty$) reduces to the condition that the wave function vanishes whenever any of the two particles touch.

The time-dependent Schrödinger equation (1) can be solved exactly by employing the Fermi-Bose mapping operator [9,12],

$$\hat{O}_c = \prod_{1 \leq i < j \leq N} \left[\text{sgn}(x_j - x_i) + \frac{1}{c} \left(\frac{\partial}{\partial x_j} - \frac{\partial}{\partial x_i} \right) \right]. \quad (4)$$

If we find a fully antisymmetric (fermionic) wave function ψ_F which obeys

$$i \frac{\partial \psi_F}{\partial t} = - \sum_{i=1}^N \frac{\partial^2 \psi_F}{\partial x_i^2}, \quad (5)$$

then the wave function

$$\psi_{B,c} = \mathcal{N}_c \hat{O}_c \psi_F, \quad (6)$$

where \mathcal{N}_c is a normalization constant, obeys Eq. (1) [9,12,13].

This means that free expansion solutions can be found by using the Fourier transform. Let

$$\begin{aligned} \psi_F(x_1, \dots, x_N, t) &= \int dk_1 \cdots dk_N \\ &\times \tilde{\psi}_F(k_1, \dots, k_N) \exp \left\{ i \sum_{j=1}^N [k_j x_j - \omega(k_j) t] \right\}, \end{aligned} \quad (7)$$

where $\omega(k) = k^2$, denote an antisymmetric wave function ψ_F , which evidently obeys Eq. (5); here

$$\begin{aligned} \tilde{\psi}_F(k_1, \dots, k_N) &= \frac{1}{(2\pi)^N} \int dx_1 \cdots dx_N \\ &\times \psi_F(x_1, \dots, x_N, t=0) \exp \left(-i \sum_{j=1}^N k_j x_j \right) \end{aligned} \quad (8)$$

is the Fourier transform of ψ_F at $t=0$ [13]. By acting with the Fermi-Bose mapping operator on ψ_F [see Eq. (6)], we obtain a time-dependent wave function of a freely expanding LL gas

$$\begin{aligned} \psi_{B,c}(x_1, \dots, x_N, t) &= \int dk_1 \cdots dk_N G(k_1, \dots, k_N) \\ &\times \exp \left\{ i \sum_{j=1}^N [k_j x_j - k_j^2 t] \right\}, \end{aligned} \quad (9)$$

where

$$G(k_1, \dots, k_N) \equiv \mathcal{N}_c \tilde{\psi}_F(k_1, \dots, k_N) \times \prod_{1 \leq i < j \leq N} \left[\operatorname{sgn}(x_j - x_i) + \frac{i}{c}(k_j - k_i) \right]. \quad (10)$$

The information on initial conditions is contained in $G(k_1, \dots, k_N)$ [that is, within $\tilde{\psi}_F(k_1, \dots, k_N)$]. If we know $G(k_1, \dots, k_N)$ in R_1 , by calculating the Fourier transform in Eq. (9), we find the wave function $\psi_{B,c}$ at some finite time $t > 0$ in R_1 . In Ref. [13], $\tilde{\psi}_F(k_1, \dots, k_N)$ was found to be proportional to the projection coefficients $b(k_1, \dots, k_N)$ of the initial bosonic wave functions onto the LL eigenstates in free space. This connection allows us to calculate $G(k_1, \dots, k_N)$ for a few particles, which are in the ground state of a LL gas in a box potential [25], and to study free expansion from such an initial state; this is performed in Sec. IV and in the Appendix. For clarity, it should be noted that $G(k_1, \dots, k_N)$ also depends on the coordinates x_j through the $\operatorname{sgn}(x_j - x_i)$ terms [$G(k_1, \dots, k_N)$ is not the Fourier transform of the bosonic wave function [13]].

In principle, from the time-dependent LL wave function $\psi_{B,c}(x_1, \dots, x_N, t)$, one can extract the physically relevant observables (in practice, this is a difficult task). Here we consider one-body observables contained within the reduced single-particle density matrix (RSPDM),

$$\rho_{B,c}(x, y, t) = N \int dx_2 \cdots dx_N \psi_{B,c}(x, x_2, \dots, x_N, t)^* \times \psi_{B,c}(y, x_2, \dots, x_N, t). \quad (11)$$

The SP density in real space is simply $\rho_{B,c}(x, x, t)$, whereas the momentum distribution is defined as

$$n_B(k, t) = \frac{1}{2\pi} \int dx dy e^{ik(x-y)} \rho_{B,c}(x, y, t). \quad (12)$$

The eigenfunctions of the RSPDM $\Phi_i(x, t)$ are called the natural orbitals (NOs),

$$\int dx \rho_{B,c}(x, y, t) \Phi_i(x, t) = \lambda_i(t) \Phi_i(y, t), \quad i = 1, 2, \dots \quad (13)$$

the eigenvalues $\lambda_i(t)$ are the occupancies of these orbitals. Apparently, in a nonequilibrium situation, the effective single-particle states $\Phi_i(x, t)$ and their occupancies $\lambda_i(t)$ may change in time.

III. ASYMPTOTIC FORM OF THE MOMENTUM DISTRIBUTION

In this section, we derive the asymptotic form of the momentum distribution of a Lieb-Liniger gas after free expansion from an initially localized state defined by $G(k_1, \dots, k_N)$ [we should keep in mind that $G(k_1, \dots, k_N)$ also depends upon the coordinates x_j via the sgn functions; see Eq. (10)]. The momentum distribution defined in Eq. (12) can be rewritten by using Eqs. (9) and (11) as

$$\begin{aligned} n_B(k) &= \frac{N}{2\pi} \int dx dy e^{ik(x-y)} \int dx_2 \cdots dx_N \times \left\{ \int dk_1 \cdots dk_N G(k_1, \dots, k_N) \exp \left[i \sum_{j=1}^N (k_j x_j - k_j^2 t) \right] \right\}_{x_1=x}^* \\ &\times \left\{ \int dq_1 \cdots dq_N G(q_1, \dots, q_N) \exp \left[i \sum_{j=1}^N (q_j x_j - q_j^2 t) \right] \right\}_{x_1=y} \\ &= \frac{N}{2\pi} \int dx_2 \cdots dx_N \int dx dy dk_1 \cdots dk_N dq_1 \cdots dq_N \times G(k_1, \dots, k_N)^*|_{x_1=x} G(q_1, \dots, q_N)|_{x_1=y} e^{i\phi}, \end{aligned} \quad (14)$$

where the phase ϕ is

$$\begin{aligned} \phi(k_1, \dots, k_N, q_1, \dots, q_N, x, y) &= - \sum_{j=2}^N (k_j x_j - k_j^2 t) + \sum_{j=2}^N (q_j x_j - q_j^2 t) - k_1 x + k_1^2 t + q_1 y \\ &\quad - q_1^2 t + k(x - y). \end{aligned}$$

The integrals over $k_1, \dots, k_N, q_1, \dots, q_N, x, y$ in Eq. (14) are evaluated with the stationary phase approximation. The point of stationary phase is defined by the following equations:

$$\frac{\partial \phi}{\partial k_j} \Big|_{k'_j} = \frac{\partial \phi}{\partial q_j} \Big|_{q'_j} = \frac{\partial \phi}{\partial x} \Big|_{x'} = \frac{\partial \phi}{\partial y} \Big|_{y'} = 0, \quad \text{for } 1 \leq j \leq N.$$

The stationary phase point is

$$k'_j = q'_j = x_j/(2t), \quad \text{for } 2 \leq j \leq N,$$

$$k'_1 = q'_1 = k,$$

$$x' = y' = 2kt. \quad (15)$$

The phase ϕ can be rewritten as

$$\phi = t \sum_{j=2}^N \left[\left(k_j - \frac{x_j}{2t} \right)^2 - \left(q_j - \frac{x_j}{2t} \right)^2 \right] + [(k - k_1)x + k_1^2 t] - [(k - q_1)y + q_1^2 t]. \quad (16)$$

We notice that $\phi(k'_1, \dots, k'_N, q'_1, \dots, q'_N, x', y') = 0$. In the stationary phase approximation, the function G in Eq. (14) is evaluated at the stationary phase point defined in Eq. (15), which yields

$$\begin{aligned} n_{B,\infty}(k) &\approx \frac{N}{2\pi} \int dx_2 \cdots dx_N \left| G \left(k, \frac{x_2}{2t}, \dots, \frac{x_N}{2t} \right) \right|^2 \\ &\times \int dx dk_1 e^{i[(k-k_1)x + k_1^2 t]} \int dy dq_1 e^{-i[(k-q_1)y + q_1^2 t]} \\ &\times \left\{ \int dk_2 \exp \left[it \left(k_2 - \frac{x_2}{2t} \right)^2 \right] \right\}^{N-1} \\ &\times \left\{ \int dq_2 \exp \left[-it \left(q_2 - \frac{x_2}{2t} \right)^2 \right] \right\}^{N-1} \\ &\propto N \int dx_2 \cdots dx_N \left| G \left(k, \frac{x_2}{2t}, \dots, \frac{x_N}{2t} \right) \right|^2 \\ &\times e^{ik^2 t} e^{-ik^2 t} \left(\sqrt{\frac{\pi}{t}} e^{i\pi/4} \right)^{N-1} \left(\sqrt{\frac{\pi}{t}} e^{-i\pi/4} \right)^{N-1}. \end{aligned} \quad (17)$$

It is convenient now to introduce variables $\xi_j = x_j/t$; from Eq. (17), we obtain the asymptotic form of the momentum distribution of a freely expanding LL gas

$$n_{B,\infty}(k) \propto \int d\xi_2 \cdots d\xi_N |G(k, \xi_2/2, \dots, \xi_N/2)|^2. \quad (18)$$

We note that in the asymptotic regime, the momentum distribution acquires the same functional form as the asymptotic SP density. In the asymptotic regime, the SP density exhibits self-similar (ballistic) expansion (this is not true in the transient period preceding the asymptotic regime; see Ref. [14]). It is most convenient to express the asymptotic SP density in variable $\xi = x/t$ (see Ref. [13]),

$$\rho_\infty(\xi) \propto \int d\xi_2 \cdots d\xi_N |G(\xi/2, \xi_2/2, \dots, \xi_N/2)|^2. \quad (19)$$

We normalize $\rho_\infty(\xi)$ such that $\int \rho_\infty(\xi) d\xi = N$. The variable $\xi = x/t$ has units of velocity; the self-similar asymptotic SP density can be interpreted as the distribution of velocities of particles in a gas, which is in a simple manner related to the momentum distribution $n_{B,\infty}(k)$.

Equation (18) can be thought of as a generalization of the dynamical fermionization of the momentum distribution which has been demonstrated for a freely expanding TG gas ($c \rightarrow \infty$) [15,16]. Free expansion in the TG regime is solved by the Fermi-Bose mapping [1,26]. In this regime, the SP density is identical on both sides of the map. Since fermions are noninteracting, the asymptotic form of the SP density (for both TG bosons and free fermions) is identical to the fermionic momentum distribution, which does not

change in time. Equations (18) and (19) immediately yield that the asymptotic momentum distribution for TG bosons has the same shape as the asymptotic SP density, which has the shape of the fermionic momentum distribution, i.e., we obtain the result in Refs. [15,16]. We also note that the equivalent relation between the asymptotic SP density and momentum distribution was found in Ref. [22] for a different model with emphasis that the time-of-flight measurements do not give the initial momentum distribution. The derived formula (18) is verified numerically on a particular example in Sec. IV.

IV. FREE EXPANSION FROM A BOX: DYNAMICS OF THE MOMENTUM DISTRIBUTION AND THE OCCUPANCIES $\lambda_i(t)$

In this section, we calculate free expansion of three LL bosons, which are initially (at $t=0$) in the ground state in an infinitely deep box of length $L = \pi$. The analytical expression for the LL box ground state has been found in Ref. [25]. By using this result, it is straightforward to calculate $G(k_1, k_2, k_3)$ (which depends on the interaction strength c) for this particular initial condition; we have outlined this calculation in the Appendix for N particles. The next step is the calculation of the Fourier integral in Eq. (9), which is performed numerically by employing the fast Fourier-transform algorithm. From the numerically obtained LL wave function $\psi_{B,c}(x_1, x_2, x_3, t)$, we calculate the momentum distribution $n_B(k, t)$, the SP density $\rho_c(x, t)$, natural orbitals, and their occupancies and study their evolution during free expansion from the box ground state.

First, let us explore the dynamics of the wave function $\psi_{B,c}(x_1, x_2, x_3, t)$. Figure 1 displays contour plots of the probability density $|\psi_{B,c}(0, x_2, x_3, t)|^2$ for $c=1$, at two different times $t=0$ and $t=3$. We see that as the LL gas expands, the probability density decreases at the hyperplanes $x_i = x_j$ ($i \neq j$) where the particles are in contact. This is in agreement with the result in Ref. [13], where it was shown (by using the stationary phase approximation) that the leading term of $\psi_{B,c}(\xi_1 t, \xi_2 t, \xi_3 t, t)$ has Tonks-Girardeau form for sufficiently large t ; that is, the leading term is zero for $\xi_i = \xi_j$ ($i \neq j$). However, this does not necessarily mean that the properties of such an asymptotic state correspond to the properties of a TG gas, which was usually studied in the ground state of some external potential. For example, suppose that the initial state is a weakly correlated ground state in the box; despite the fact that during expansion, the particles get strongly correlated in the close vicinity of the hyperplanes of contact, the absence of correlations in the initial state survives as an overall feature through to the asymptotic state (see the discussion in Ref. [13] and the second item in Ref. [12]). Thus, even though the asymptotic state is described by a wave function with the TG structure, the physical properties of the expanded gas can considerably differ from the properties of a TG gas.

In order to further study the properties of the state in expansion, Fig. 2 illustrates the occupation of the lowest natural orbital in time $\lambda_1(t)$ for several values of c . The asymptotic values of the occupancies, which are obtained by

FIG. 1. (Color online) Contour plots of $|\psi_{B,c}(0, x_2, x_3, t)|^2$ for $c=1$ at (a) $t=0$ and (b) $t=3$. As the time t increases, the probability density at the hyperplanes where particles are in contact decreases.

FIG. 2. (Color online) The lowest natural orbital $\lambda_1(t)$ as a function of time for three values of c . Red diamonds (dashed line) is for $c=0.25$, black circles (solid line) for $c=1$, and blue squares (dotted line) for $c=5$; the lines connecting the markers are guides for the eyes. The corresponding horizontal lines without markers denote the asymptotic occupancies calculated from the asymptotic wave functions [13].

FIG. 3. (Color online) Evolution of the x -space density in time for various interaction strengths c : (a) $c=0.25$ at $t=0$ (red dotted line), $t=2$ (solid black line), and $t=4$ (blue dashed line); (b) $c=1$ at $t=0$ (red dotted line), $t=2$ (solid black line), and $t=4$ (blue dashed line); (c) $c=10$ at $t=0$ (red dotted line), $t=1$ (solid black line), $t=3$ (blue dashed line). The asymptotic x -space density $\rho_\infty(\xi)$ (circles) is plotted as a function of $x = \xi t$ corresponding to the largest time in each subplot.

using the asymptotic forms of the wave functions [13] are indicated with horizontal lines. We observe that the occupancy of the leading NO, $\lambda_1(t)$, decreases during time evolution. However, for the plotted interaction strengths, the decrease of $\lambda_1(t)$ is not too large. This means that the coherence of the system (described by the occupations of the natural orbitals) for the plotted parameters only partially decreases during free expansion due to the interactions. It should be noted that in the TG limit $c \rightarrow \infty$, for hard-core bosons on the lattice [15], it has been shown that the leading natural orbitals slightly increase during free expansion [15], which differs

FIG. 4. (Color online) Evolution of the momentum distribution in time for various interaction strengths c . The lines and colors for different values of c and t are identical as in Fig. 3. Solid black and blue dashed lines are almost indistinguishable.

from the finite c results obtained here. It is reasonable to associate the decrease of $\lambda_1(t)$ to the change in the LL wave functions at the hyperplanes of contact; this change does not occur in the TG regime, where the wave functions are zero at the contact hyperplanes at any time of the expansion.

Let us explore the dynamics of the momentum distribution $n_B(k,t)$ and its connection to the SP density $\rho_c(x,t)$ at large times t . The time evolution of $\rho_c(x,t)$ and $n_B(k,t)$ is illustrated in Figs. 3 and 4; we display x - and k -space densities for various values of the parameter c at several times t . Initially, all momentum distributions have a typical bosonic property: they peak at $k=0$. We observe that the qualitative changes in the shape of $n_B(k,t)$ are more pronounced for larger values of c . Circles in Figs. 3 and 4 show the asymptotic values calculated by using Eqs. (18) and (19). We see that at the maximal value of time t in the plots, the momentum distribution agrees well with that obtained with

FIG. 5. (Color online) Asymptotic expansion velocity ξ_∞ (squares, dashed line) and the square root of the total energy \sqrt{E} (circles, solid line) for various interaction strengths c ; lines serve as guides for the eyes (see text for details).

the stationary phase approximation in Eq. (18). Our numerical calculation is in agreement with the findings presented in Eqs. (18) and (19). We would like to point out that, even though the observables $n_B(k,t)$ and $\rho_c(x,t)$ are well approximated by the stationary phase approximation at the maximal time reached in our numerical simulations (see Figs. 3 and 4), the system is strictly speaking not yet fully in the asymptotic regime (e.g., note that the occupancies of the natural orbitals have not reached their asymptotic values) and even better agreement should be expected at larger times. Unfortunately, the maximal time allowed in our numerical calculations is limited by the computer memory and time.

In order to further study the asymptotic forms of the momentum distribution and the SP density, let us calculate the asymptotic expansion velocity as a function of the interaction parameter c . Since different parts of the cloud expand at different velocities, a definition of this quantity has a certain degree of freedom. Here, we define this quantity as a root mean square of the asymptotic SP density [49] in variable $\xi=x/t$ (i.e., velocity),

$$\xi_\infty = \sqrt{\frac{1}{N} \int \xi^2 \rho_\infty(\xi) d\xi}, \quad (20)$$

the factor $1/N$ simply reflects the fact that $\rho_\infty(\xi)$ is normalized to the number of particles N . The asymptotic velocity ξ_∞ is connected to the total energy E stored in the system. During free expansion, the interaction energy is transferred to the kinetic energy; in the asymptotic regime all of the energy is kinetic, and it can be expressed via the momentum distribution

$$E = \int k^2 n_{B,\infty}(k) dk. \quad (21)$$

By using Eqs. (18) and (19), we obtain

$$\xi_\infty = \sqrt{\frac{4}{N} \sqrt{E}}, \quad (22)$$

that is, $E = N \xi_\infty^2 / 4$ which is the classical expression for the kinetic energy of N particles with velocity ξ_∞ and mass $1/2$

[recall that we use units where the kinetic-energy operator in Eq. (1) is $-\sum_{i=1}^N \partial^2 / \partial x_i^2$]. The quantities \sqrt{E} and ξ_∞ are displayed in Fig. 5 for various values of the interaction strength c ; the plots underpin Eq. (22). The total energy was calculated simply as $E=q_1^2+q_2^2+q_3^2$ where quasimomenta q_i are obtained by solving transcendental Bethe equations for the initial state [25] (see the Appendix). The asymptotic velocity was obtained via Eq. (20) by numerical integration. Our numerical calculations are in good agreement (better than 99%) with Eq. (22); we attribute the discrepancy to the inaccuracy of the numerical integration.

V. CONCLUSION

We have numerically studied free expansion of a few Lieb-Liniger bosons, which are initially in the ground state of an infinitely deep hard-wall trap. This numerical calculation has been carried out by employing a standard Fourier transform, as follows from the Fermi-Bose transformation for a time-dependent Lieb-Liniger gas. We have studied the evolution of the momentum distribution, the real-space single-particle density, and the occupancies of natural orbitals: both in the nontrivial transient regime of the expansion and asymptotically. We have derived analytically (by using the stationary phase approximation) the formula which connects the asymptotic shape of the momentum distribution and the initial state. For sufficiently large times, the momentum distribution coincides (up to a scaling transformation) with the shape of the real-space single-particle density (the expansion is asymptotically ballistic). This result can be considered as a generalization of the dynamical fermionization of the momentum distribution in the Tonks-Girardeau regime, which has been pointed to occur in the course of free expansion [15,16]. We have shown that the occupancy of the lowest natural orbital of the system decreases with time while approaching its asymptotic value. This was related to the buildup of correlations of the hyperplanes of contact of the particles. Finally, we have calculated the expansion velocity in asymptotic regime and pointed out its relation to the overall energy of the system.

In order to gain further understanding of a freely expanding LL gas, it would be desirable to investigate transient dynamics of the observables for larger number of particles and also for different initial conditions (e.g., the ground state of a LL gas in different initial trapping potentials).

APPENDIX: THE FUNCTION $G(k_1, \dots, k_N)$ FOR THE BOX GROUND STATE

In Sec. IV, we have studied free expansion of three LL bosons, which are initially (at $t=0$) in the ground state in an infinitely deep box of length $L=\pi$. Here we present exact analytical expression for function $G(\{k\}) \equiv G(k_1, \dots, k_N)$ for this particular case. First, we use the connection between $\tilde{\psi}_F(k_1, \dots, k_N)$ and the projection coefficients $b(k_1, \dots, k_N)$ of the initial bosonic wave functions onto the LL eigenstates in free space [13] to rewrite the expression for G ,

$$G(\{k\}) = N! \mathcal{N}(\{k\}) b(\{k\}) \times \prod_{1 \leq i < j \leq N} \left[\text{sgn}(x_j - x_i) + \frac{i}{c}(k_j - k_i) \right]. \quad (\text{A1})$$

Here, $\mathcal{N}(\{k\})$ is the normalization constant for LL eigenstates in free space [38],

$$\frac{1}{\mathcal{N}(\{k\})} = \sqrt{(2\pi)^N N! \prod_{i < j} \left[1 + \left(\frac{k_j - k_i}{c} \right)^2 \right]}, \quad (\text{A2})$$

and coefficients $b(\{k\})$ are found by using the solution for the LL box ground state [25],

$$b(\{k\}) \propto \mathcal{N}(\{k\}) \sum_{P'} (-1)^{P'} \prod_{1 \leq i < j \leq N} \left[1 - \frac{i}{c}(k_{P'j} - k_{P'i}) \right] \times \sum_{\{\epsilon\}} \sum_P \epsilon_1 \cdots \epsilon_N \prod_{1 \leq i < j \leq N} \left(1 - \frac{ic}{q_i + q_j} \right) \times \left(1 + \frac{ic}{q_{P_i} - q_{P_j}} \right) \int_{-L/2}^{L/2} dx_1 \int_{x_1}^{L/2} dx_2 \cdots \int_{x_{N-1}}^{L/2} dx_N \times \exp \left\{ i \sum_{j=1}^N \left[(q_{P_j} - k_{P'j}) x_j - q_{P_j} \frac{L}{2} \right] \right\}. \quad (\text{A3})$$

In the expression above, summations are taken over all permutations P and P' which are of order N , whereas the set $\{\epsilon\}$ is defined such that each ϵ_i is either $+1$ or -1 (here $i=1, \dots, N$, i.e., there are 2^N combinations in the set $\{\epsilon\}$). The ground-state quasimomenta are defined as $q_i = \epsilon_i |q_i|$, for $i=1, \dots, N$, and their magnitudes $|q_i|$ are found by solving (numerically) the system of coupled transcendental equations [25],

$$|q_i|L = \pi + \sum_{j \neq i} \left(\tan^{-1} \frac{c}{|q_i| - |q_j|} + \tan^{-1} \frac{c}{|q_i| + |q_j|} \right). \quad (\text{A4})$$

Finally, let us mention that the constant of proportionality in Eq. (A3) is fixed such that the wave function $\psi_{B,c}$ is properly normalized.
