ABSTRACT: We compute the cross section for photons emitted from sea quarks in proton-nucleus collisions at collider energies. The computation is performed within the dilute-dense kinematics of the Color Glass Condensate (CGC) effective field theory. Albeit the result obtained is formally at next-to-leading order in the CGC power counting, it provides the dominant contribution for central rapidities. We observe that the inclusive photon cross section is proportional to all-twist Wilson line correlators in the nucleus. These correlators also appear in quark-pair production; unlike the latter, photon production is insensitive to hadronization uncertainties and therefore more sensitive to multi-parton correlations in the gluon saturation regime of QCD. We demonstrate that k_{\perp} and collinear factorized expressions for inclusive photon production are obtained as leading twist approximations to our result. In particular, the collinearly factorized expression is directly sensitive to the nuclear gluon distribution at small x . Other results of interest include the realization of the Low-Burnett-Kroll soft photon theorem in the CGC framework and a comparative study of how the photon amplitude is obtained in Lorenz and light-cone gauges.

1 Introduction

Photons produced in proton-nucleus (p+A) collisions are powerful probes of the fundamental many-body structure of strongly interacting matter. Sufficiently energetic photons, in particular, are free of the uncertainties that attend the fragmentation of partons into hadrons. Further, the information on microscopic dynamics that is probed by photon final states complements in fundamental ways the information accessible in deeply inelastic scattering (DIS) experiments off hadrons and nuclei. A global analysis of photon production in DIS and p+A collisions, analogous to those performed for currently for parton distribution functions has therefore the potential to reveal universal features of parton dynamics that are distinct from those that are particular to the scattering process.

The photons produced in deuteron-nucleus collisions at the ultrarelativistic energies of the Relativistic Heavy Ion Collider (RHIC) and p+A collisions at the Large Hadron Collider (LHC) are uniquely sensitive to strongly correlated states of gluons in which the gluons have the maximal occupancy allowed by QCD. The dynamics of these saturated gluon states is described by the Color Glass Condensate (CGC) [1–3], a classical effective theory of QCD in the high energy asymptotics (of high center of mass energies and small

Figure 1. Leading order process for prompt photon production in proton-nucleus collisions. The diagram describes the bremsstrahlung of a photon from a valence quark after multiple scattering off the classical gluon field in the nucleus.

values of parton momentum fractions x) that may be applicable for significant kinematic windows at RHIC and LHC.

A characteristic feature of the CGC is that the dynamics of saturated gluons is governed by an emergent “saturation scale” $Q_S(x)$, which grows with increasing energy, or equivalently, decreasing x . Modes in hadron/nuclear wavefunctions with $k_\perp < Q_S$ are maximally occupied with an occupancy that is parametrically $1/\alpha_S$, where α_S is the QCD fine structure constant. In contrast, the modes $k_\perp \gg Q_S$ have small occupancies and interact dynamically as the partons of perturbative QCD (pQCD). If Q_S is large relative to the intrinsic non-perturbative QCD scale, the strongly correlated dynamics of gluons can be computed using weak coupling techniques. In nuclei, the saturation scale $(Q_S^A)^2 \sim A^{1/3}$. The high energy dynamics of nuclei are therefore well suited to test the CGC description of high energy QCD. Photon production, as noted, is a particularly sensitive probe because it is independent of the details of how partons fragment into hadrons.

Photon production in p+A collisions was previously computed to leading order in the CGC framework [4]. See also [5]. A derivation within the dipole formalism can be found in [6, 7]. Using this result, the forward prompt photon spectrum was calculated in [8]. Further applications include the photon-hadron [9, 10] and the photon-jet correlations [11] at forward rapidity.

The power counting for proton-nucleus collisions corresponds to a “dilute-dense” limit, where contributions to lowest order in $Q_S^p/k_{1\perp} \ll 1$ (where Q_S^p is the saturation scale in the projectile proton) are preserved along with all order terms in $Q_S^A/k_{1\perp}$. Here $k_{1\perp}, k_{2\perp}$ respectively correspond to the momentum exchange from the proton and the nucleus to the final state of interest. For photon production, the leading term in this dilute-dense power counting corresponds to order $O(\alpha)$, where α_e is the QED fine structure constant. This leading order (LO) contribution is illustrated in figure 1. The quark line in this figure corresponds to a valence quark in the wavefunction of the projectile proton. In the high occupancy regime of $k_\perp \leq Q_S^A$, there is no α_S dependence at LO because the α_S factor in the cross section arising from the coupling of a gluon to the valence quark is compensated by the $1/\alpha_S$ occupancy of these gluons in the target. The $O(\alpha)$ dependence must be understood as being accompanied by the valence quark distribution f_q in the proton.

At next-to-leading order (NLO) $O(\alpha_e \alpha_S)$, there are a number of contributions which can be classified into the three classes shown in figure 2. The leftmost diagram (class I)

Figure 2. Next-to-leading order processes for prompt photon production in proton-nucleus collisions. The class I diagram describes the bremsstrahlung of a photon from a valence quark. The next two diagrams correspond to a gluon from the proton splitting into a $q\bar{q}$ that annihilates into a photon final state (class II), or emits a photon either before or after rescattering off the nucleus (class III). As described in the text, the class I diagram, upon evolution, is the same order as the diagram in figure 1.

corresponds to a gluon emitted from the incoming valence quark. For inclusive photon production, one has to integrate over the phase space corresponding to the emitted gluon. Another NLO contribution to inclusive photon production in this diagrammatic class (not shown) arises from the interference between the LO contribution in the amplitude and a contribution in the complex conjugate amplitude corresponding to the virtual emission and absorption of a gluon by the valence quark. Since both of these diagrams are of a bremsstrahlung type, the divergence structure is inherited from NLO quark production, investigated in detail in ref. [12]. The resulting expression gives logarithms that are sensitive to the transverse momentum and x of the gluon as well as finite pieces. These diagrams contribute to the double-log DGLAP renormalization group (RG) evolution of the valence quark distribution.¹ The finite pieces can be absorbed in the definition of the quark distribution function by appropriate choice of factorization scale and by choice of factorization scheme. The NLO contributions of class I are therefore actually of $O(\alpha_e)$ if the bare valence quark distribution in the proton is replaced by the RG evolved quark distribution.

The class II diagram in figure 2 was computed recently [13]. In this case, since the quark-antiquark pair are emitted from the gluon prior to their subsequent annihilation into the photon. At small- x kinematics, this diagram is of order $O(\alpha_e\alpha_S)$ with the cross section for this contribution accompanied by a factor f_g corresponding to the gluon distribution in the proton. The emission of the initial gluon from the valence quark line is of order $\alpha_S \log 1/x \sim 1$ at small- x where it does not contribute to the power counting. While this is an NLO diagram, it can in principle provide a much larger contribution to photon production. This is because the gluon distribution grows rapidly while the valence quark distribution decreases at small x , giving $f_g \gg f_q$. Thus for photon production in the small x kinematics of the projectile proton, such NLO contributions can dominate significantly. The kinematics of the class II diagram is relevant for inclusive photon production at central

¹The dominant contribution comes from the large phase space in transverse momentum $\alpha_S \ln(k_\perp) \sim 1$; since valence quarks are predominantly localized at $x \sim 1$, the logarithms in x are sub-dominant, as is the case for DGLAP evolution.

rapidities. Because of pair annihilation, the transverse momentum of the photon for this diagram is strongly constrained to be dominated by momenta around $k_{\gamma\perp} \sim Q_S^A$. Thus this contribution is in principle very sensitive to the saturation scale of the nucleus.

However as also noted in ref. [13], there is a further class of NLO processes, class III in figure 2, that contribute significantly to photon production in p+A collisions. Firstly, like the class II process, this NLO contribution comes accompanied by a factor f_g which, as noted, will overwhelm the LO contribution at small x . Secondly there are some features of the class III computation that are qualitatively different from those of class II. Unlike the latter, photon production, while sensitive to Q_S^A , is dominated by soft momenta with $k_{\perp} < Q_S^A$. Similarly, since photon production is not as kinematically constrained for class III diagrams relative to class II diagrams, it will also dominate at large $k_{\gamma\perp} > Q_S^A$. In particular, class III diagrams will match the contribution from leading twist pQCD at high $k_{\gamma\perp}$, while the class II contribution is proportional to a higher twist four point correlator even at large $k_{\gamma\perp}$. The sum of class II and class III diagrams constitute the relevant NLO contribution to inclusive photon production in the CGC framework.

In this paper, we will compute the class III NLO diagrams for photon production in p+A collisions in the CGC framework.² We will perform the computation first in Lorenz gauge $\partial_\mu A^\mu = 0$ gauge, and subsequently in light-cone gauge $A^+ = 0$. In addition to being an independent non-trivial check of our results, the intermediate steps are interesting and realized differently in the two gauges.

The paper is organized as follows. In section 2, after a preliminary discussion of dilute-dense collisions in the CGC framework, we will outline the derivation of the amplitude for the inclusive production of a $q\bar{q}\gamma$ final state in Lorenz gauge. Our work closely follows the previous derivation in this gauge of the amplitude for gluon production [15] and quark-antiquark pair production [16] in proton-nucleus collisions. As for the case of the pair production amplitude considered previously, we show that contributions from so-called “singular” terms, wherein the photon is produced from within the target, are exactly canceled by terms that one can identify as gauge artifacts in regular terms. The latter are contributions where the quark-antiquark pair (and the photon) are produced either before or after the scattering of gluons from the target off the projectile.

In section 3, we compute the cross section for inclusive photon production. For readers interested in the central result of this work, the key expression is given in eq. (3.17). As in the case of quark-antiquark production [16], the cross section factorizes into the product of the unintegrated gluon distribution in the projectile times the sum of terms corresponding to the gluon distribution in the target, and quark-antiquark-gluon and quark-antiquark-quark-antiquark light-like Wilson line correlators. These correlators contain non-trivial information on many-body gluon and sea quark correlations that are of all twist order in conventional pQCD language. In section 4 we demonstrate that for $Q_S^A \ll k_{2\perp}$, the cross section can be expressed as a k_{\perp} factorized product of unintegrated gluon distributions in the projectile and target [17, 18]. We show explicitly that the corresponding leading twist

²Several of the results presented here were first obtained as a part of the Masters’s thesis of one of the authors (Garcia-Montero) at the University of Heidelberg [14].

k_{\perp} factorized amplitude agrees exactly with the expression derived recently by Motyka, Sadzikowski and Stebel [18] in the context of Z^0 boson hadroproduction. Taking the limit $k_{1\perp}, k_{2\perp} \rightarrow 0$, one recovers the formal structure of the leading collinear factorization contribution to inclusive photon production from gluon-gluon scattering [19]. This demonstrates the unique sensitivity of inclusive photon production to the nuclear gluon distribution function at small x . Unfortunately, the detailed analytical comparison of the two expressions is cumbersome; a numerical comparison is left for future work. In section 5, we summarize our results and provide a detailed outline of the necessary ingredients for the numerical computation of inclusive photon production in proton-nucleus collisions. We will leave this numerical computation for a subsequent publication.

In A we will compute the amplitude for inclusive photon production in light-cone gauge $A^+ = 0$. This computation follows a previous computation of gluon production in this gauge [20]. Unlike gluon production, where the amplitudes in Lorenz gauge and light-cone gauge differ (albeit the cross sections of course agree), in this case, the amplitudes in the two gauges agree exactly. Some properties of the amplitude are outlined in B. In addition to demonstrating that this amplitude satisfies a Ward identity, we show in particular that the well known Low-Burnett-Kroll theorem [21–23] is satisfied. This corresponds, in the soft photon limit, to the factorization of the amplitude into the amplitude for quark-antiquark production times a contribution determined by the Lorentz structure of the photon.

2 Amplitude for inclusive $q\bar{q}\gamma$ production in the Lorenz gauge

In the CGC effective theory, the gluon dynamics with high occupancy at small x are described by the classical Yang-Mills equations. For collisions of the proton moving in the positive z direction and the nucleus moving in the negative z direction at the speed of light, the Yang-Mills equations are

$$[D_{\mu}, F^{\mu\nu}](x) = g\delta^{\nu+}\delta(x^-)\rho_p(\mathbf{x}_{\perp}) + g\delta^{\nu-}\delta(x^+)\rho_A(\mathbf{x}_{\perp}), \quad (2.1)$$

where ρ_p and ρ_A correspond to the static and stochastic color charge density matrices at large x in the proton and the nucleus, respectively. This framework is feasible at a given impact parameter for three different regimes of color charge densities depending on the energy of the collision and the kinematic regime of interest. These correspond to the dilute-dilute ($\rho_p/k_{1\perp}^2 \ll 1, \rho_A/k_{2\perp}^2 \ll 1$), the dilute-dense ($\rho_p/k_{1\perp}^2 \ll 1, \rho_A/k_{2\perp}^2 \sim 1$), and the dense-dense ($\rho_p/k_{1\perp}^2 \sim 1, \rho_A/k_{2\perp}^2 \sim 1$) regimes. To compute inclusive cross sections, the modulus squared of the computed amplitude must be averaged over the color sources, thereby replacing $\rho_p, \rho_A \rightarrow Q_S^p, Q_S^A$ in the power counting. Subsequent to this averaging, the dilute-dilute limit in the CGC effective theory can be matched to the leading twist frameworks of pQCD at small x . Further, the dilute-dense limit corresponds to the dominance of leading twist contributions on the proton side with all twist contributions on the nuclear side, and the dense-dense limit includes all twist contributions from both the proton and the nucleus to the scattering process of interest.

At the collider energies currently accessible in p+A collisions, the appropriate dynamics is that of the dilute-dense limit. The nucleus is dense because there is an enhancement of the

order of $A^{1/3}$ in the number of color sources even at large x . These sources can all radiate soft gluons that further function as color sources for even softer gluons. In the proton, on the other hand, there are $O(1)$ color sources, and it is only at very large rapidities relative to the proton fragmentation region that the density of color sources becomes $\rho_p/\mathbf{k}_{1\perp}^2 \sim 1$. Alternately, the dense-dense regime can be attained in very rare high multiplicity events where the proton fluctuates into sources of color charge already at large x .

In this work, we will be interested in photon production in p+A collisions at collider energies for the small x kinematics, and in event classes where the dilute-dense asymptotics is appropriate and gives the dominant contribution. Analytic computations are feasible then, and explicit expressions can be derived. In contrast, the dense-dense limit is not analytically tractable even for inclusive gluon production since there is no small parameter to expand in. Results can be obtained only through numerical simulations of the Yang-Mills equations [24–26].

2.1 Structure of the gluon field and setup of the amplitude computation

In what follows, we work entirely in the Lorenz covariant gauge $\partial_\mu A^\mu = 0$. The outline of the derivation in light-cone gauge is given in A. For a dilute-dense system with $\rho_p/\mathbf{k}_{1\perp}^2 \ll 1$ and $\rho_A/\mathbf{k}_{2\perp}^2 \sim 1$, the analytical solution of eq. (2.1) in the Lorenz gauge can be expressed in momentum space as [15]

$$A^\mu(q) = A_p^\mu(q) + \frac{ig}{q^2 + iq^+\epsilon} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} e^{i(\mathbf{q}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \times \left\{ C_U^\mu(q, \mathbf{k}_{1\perp}) [U(\mathbf{x}_\perp) - 1] + C_V^\mu(q) [V(\mathbf{x}_\perp) - 1] \right\} \frac{\rho_p(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2}, \quad (2.2)$$

where $A_\mu(q) = A_\mu^a(q)T^a$ and T^a are the generators of $SU(N_c)$ in the adjoint representation. We will also use a shorthand notation, $\int_{\mathbf{k}_\perp} \equiv \int \frac{d^2\mathbf{k}_\perp}{(2\pi)^2}$ and $\int_{\mathbf{x}_\perp} \equiv \int d^2\mathbf{x}_\perp$, hereafter. In detail, the ingredients going into eq. (2.2) are as follows. The first term, $A_p^\mu(q)$, represents the gluon field of the proton alone

$$A_p^\mu(x) = -g\delta^{\mu+}\delta(x^-)\frac{1}{\nabla_\perp^2}\rho_p(\mathbf{x}_\perp). \quad (2.3)$$

The vectors C_U^μ and C_V^μ are abbreviated forms for the momentum dependence of the integral, with $\mathbf{k}_{1\perp}$ being the momentum exchanged from the proton, while $\mathbf{k}_{2\perp} \equiv \mathbf{q}_\perp - \mathbf{k}_{1\perp}$ exchanged from the nucleus. The explicit forms of C_U^μ and C_V^μ are

$$C_U^+(q, \mathbf{k}_{1\perp}) \equiv -\frac{\mathbf{k}_{1\perp}^2}{q^- + i\epsilon}, \quad C_U^-(q, \mathbf{k}_{1\perp}) \equiv \frac{(\mathbf{q}_\perp - \mathbf{k}_{1\perp})^2 - \mathbf{q}_\perp^2}{q^+}, \quad C_U^\perp(q, \mathbf{k}_{1\perp}) \equiv -2\mathbf{k}_{1\perp}, \quad (2.4)$$

$$C_V^+(q) \equiv 2q^+, \quad C_V^-(q) \equiv 2\frac{\mathbf{q}_\perp^2}{q^+} - 2q^-, \quad C_V^\perp(q) \equiv 2\mathbf{q}_\perp.$$

These two functions are related to the well-known Lipatov effective vertex [27–29] via the simple relation, $C_L^\mu = C_U^\mu + C_V^\mu/2$. This effective vertex is a gauge covariant expression that efficiently combines the various contributions to glue-gluon scattering in the Regge-Gribov limit of QCD.

In eq. (2.2), the Wilson lines U and V account for the modification of the gluon field of the proton due to multiple gluon scatterings in the nucleus and can be expressed, for an arbitrary light-like path as

$$U(a, b; \mathbf{x}_\perp) = \mathcal{P}_+ \exp \left[ig \int_b^a dz^+ A_A^-(z^+, \mathbf{x}_\perp) \cdot T \right], \quad (2.5)$$

$$V(a, b; \mathbf{x}_\perp) = \mathcal{P}_+ \exp \left[\frac{ig}{2} \int_b^a dz^+ A_A^-(z^+, \mathbf{x}_\perp) \cdot T \right], \quad (2.6)$$

where $A_A^-(z^+, \mathbf{x}_\perp)$ represents the gluon field alone. This field can be expressed similarly to A_p^μ above as

$$A_A^\mu(x) = -g \delta^{\mu-} \delta(x^+) \frac{1}{\nabla_\perp^2} \rho_A(\mathbf{x}_\perp). \quad (2.7)$$

In the above expressions for the Wilson lines \mathcal{P}_+ denotes path-ordering in the x^+ direction.

While U is the standard Wilson line in the adjoint representation of $SU(N_c)$, V is an unusual form of the Wilson line that turns out to be a gauge artifact of the gluon production amplitude in Lorenz gauge. This can be deduced from the fact that the V dependent terms in the amplitude do not appear in the cross sections nor in calculations in other gauges [20, 30]. While one expects therefore that V should drop out at the level of the cross section for photon production, we will show that they will not appear in our final expressions for the amplitude. The same observation was made previously for the amplitude for $q\bar{q}$ production in Lorenz gauge. We will henceforth use the following shorthand notation for the complete Wilson lines,

$$U(\mathbf{x}_\perp) \equiv U(\infty, -\infty; \mathbf{x}_\perp), \quad V(\mathbf{x}_\perp) \equiv V(\infty, -\infty; \mathbf{x}_\perp). \quad (2.8)$$

Before we proceed, it is instructive to discuss the underlying structure of eq. (2.2) in coordinate space. This can be decomposed by splitting eq. (2.2) as $A^\mu = A_R^\mu + A_S^\mu$ where A_R^μ is called a regular term and A_S^μ a singular term. The former corresponds to the emission of the gluon from the proton before interacting with the highly Lorentz contracted shock wave of gluons that comprises the nuclear target, while the latter corresponds to gluon production from within the shock wave. The latter term is proportional to the Lorentz contracted width of the nucleus $\propto \delta(x^+)$. Because $2q^- = q^2/q^+ + \mathbf{q}_\perp^2/q^+$, we can split $C_V^-(q)$, the only term with q^- dependence, into a regular part $C_{V,\text{reg}}^\mu(q)$ and a ‘‘singular’’ part

$$C_V^\mu(q) = C_{V,\text{reg}}^\mu(q) - \delta^{\mu-} \frac{q^2}{q^+}. \quad (2.9)$$

We observe that the singular field appears from the second term in eq. (2.9) because the q^2 term in eq. (2.9) cancels the $1/q^2$ pole in eq. (2.2). Clearly, the q^- integration leads to $\delta(x^+)$, but we need to be cautious about the infinitesimal longitudinal extension in $V(\mathbf{x}_\perp)$. After careful treatment, its Fourier transformed representation in coordinate space can be expressed as

$$A_S^\mu(x) = \frac{g^2}{2} A_A^\mu(x) V(x^+, -\infty; \mathbf{x}_\perp) \theta(x^-) \frac{1}{\nabla_\perp^2} \rho_p(\mathbf{x}_\perp). \quad (2.10)$$

In addition to decomposing the gauge field, we will need one more ingredient for our computation of the class III amplitude for photon production. This is the effective vertex corresponding to self-energy insertions in the time-ordered quark propagator arising from multiple insertions of the nuclear gluon background field: it is given by [16]

$$\mathcal{T}(k, p) = \begin{cases} 2\pi\delta(k^+)\gamma^+ \int_{\mathbf{x}_\perp} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp} [\tilde{U}(\mathbf{x}_\perp) - 1] & (p^+ > 0), \\ -2\pi\delta(k^+)\gamma^+ \int_{\mathbf{x}_\perp} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp} [\tilde{U}^\dagger(\mathbf{x}_\perp) - 1] & (p^+ < 0), \end{cases} \quad (2.11)$$

where p is the quark momentum and k is the momentum transfer from the multiple gluon “kicks” to the quark. The Wilson line in the fundamental representation \tilde{U} is defined as in eq. (2.5) with the $SU(N_c)$ adjoint generators T^a replaced by the generators t^a of the fundamental representation. Explicitly, it is written as [31]

$$\tilde{U}(\mathbf{x}_\perp) = \mathcal{P}_+ \exp \left[-ig^2 \int_{-\infty}^{\infty} dz^+ \frac{1}{\nabla_\perp^2} \rho_A(z^+, \mathbf{x}_\perp) \cdot t \right]. \quad (2.12)$$

The effective vertex appears in the quark propagator and \tilde{U} and \tilde{U}^\dagger sum over all the gluon insertions to the quark and the antiquark respectively. The momentum transfer from the nucleus k should be integrated over. Since the effective vertex does not change the order of the diagrams parametrically by any power of g , processes where the emitted photon is sandwiched between two such effective vertices are possible. We will see in the following that this is not the case; the kinematics of the process will constrain the number and configuration of these effective vertices.

From the above discussion, we can deduce that for the amplitude for photon production in figure 2 there are fourteen non-vanishing contributions. We will separate them in two groups of diagrams:

1. the regular terms, in which the $q\bar{q}$ pair is created from the regular field A_R^μ .
2. the singular terms, wherein the pair is spawned from A_S^μ .

In the following computation, we shall include only one insertion of $A_{R/S}^\mu$ on the quark propagator, regular or singular, to stay consistently at first order in the proton source ρ_p . As noted, the number of gluon insertions from the nucleus onto the quark and antiquark lines from the nucleus can, however, in our dilute-dense power counting, be as many as the kinematics permit. The amplitude can be decomposed into the external polarization vector of the photon and an amplitude vector, with the results in the following subsections expressed in terms of the amplitude vector defined as

$$\mathcal{M}_\lambda(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) \equiv \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma), \quad (2.13)$$

where \mathbf{q} , \mathbf{p} , and \mathbf{k}_γ are the quark, the antiquark, and the photon external three momenta, respectively, and λ is the photon polarization. We summarize in table 1 the momenta notations that will be used in the following calculations.

| | |
|--|---|
| k_1 : 4-momentum exchanged from the proton | k_2 : 4-momentum exchanged from the nucleus |
| k_γ : photon 4-momentum | k : 4-momentum from \tilde{U} |
| q : quark 4-momentum | p : antiquark 4-momentum |
| P : 4-momentum of the final state $P = k_1 + k_2 = p + q + k_\gamma$ | |
| (4-momentum from \tilde{U}^\dagger : $k_2 - k = P - k_1 - k$) | |

Table 1. Summary of momentum notations used in the text.

Figure 3. Brehmstrahlung diagrams without gluon insertions in the quark and antiquark lines.

2.2 Regular contributions to the amplitude

Following the above stated classification, we will proceed to find the regular diagrams which have no fundamental Wilson lines first. For this case, there are two diagrams, shown on figure 3, with exactly one insertion of the proton source, in the form of the regular field A_R . The two diagrams represent the scattering of a gluon off the target and the resulting creation of a $q\bar{q}$ pair. The photon is then emitted from the quark or antiquark line. Using standard Feynman rules, the vector amplitude for the diagram (R1) (denoted as \mathcal{M}_{R1}^μ) is

$$\mathcal{M}_{R1}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = \bar{u}(\mathbf{q})(-iq_f e \gamma^\mu) S_0(q + k_\gamma) (-ig A(P) \cdot t) v(\mathbf{p}), \quad (2.14)$$

where P is the total external 4-momentum

$$P \equiv p + q + k_\gamma, \quad (2.15)$$

and the quark lines are given in this calculation by the vacuum time-ordered fermion propagator

$$S_0(p) \equiv i \frac{\not{p} + m}{p^2 - m^2 + i\epsilon}. \quad (2.16)$$

The proton field A_p^μ does not contribute to this diagram. It contains the delta function $\delta(p^- + q^- + k_\gamma^-)$ which cannot be satisfied if the quark, antiquark, and photon are on-shell, as $p^-, q^-, k_\gamma^- > 0$. Dropping the A_p^μ term, we are left with the rest of A_R^μ , which, for the amplitude \mathcal{M}_{R1}^μ , gives,

$$\begin{aligned} \mathcal{M}_{R1}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= \frac{q_f e g^2}{P^2} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \\ &\times \left\{ [U(\mathbf{x}_\perp) - 1]^{ba} \not{C}_U(P, \mathbf{k}_{1\perp}) + [V(\mathbf{x}_\perp) - 1]^{ba} \not{C}_{V,\text{reg}}(P) \right\} t^b v(\mathbf{p}). \end{aligned} \quad (2.17)$$

Figure 4. Contributions for the amplitude with at most one Wilson line in the fundamental representation, either \tilde{U} or \tilde{U}^\dagger .

Following the same procedure as the one for (R1), one finds the amplitude contribution (R2) for the photon emitted from the antiquark to be

$$\begin{aligned} \mathcal{M}_{R2}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = & -\frac{q_f e g^2}{P^2} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) \left\{ [U(\mathbf{x}_\perp) - 1]^{ba} \mathcal{C}_U(P, \mathbf{k}_{1\perp}) \right. \\ & \left. + [V(\mathbf{x}_\perp) - 1]^{ba} \mathcal{C}_{V,\text{reg}}(P) \right\} \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu t^b v(\mathbf{p}). \end{aligned} \quad (2.18)$$

It will be shown in the next subsection that the singular contributions will cancel the terms with the Wilson line V — the final expression has no dependence on V .

Diagrams with one insertion of the effective vertex on the quark propagator can have one Wilson line \tilde{U} or \tilde{U}^\dagger in the fundamental representation, as shown in figure 4, for the quark [diagrams (3)–(5)] and likewise for the antiquark [diagrams (6)–(8)]. In the following steps we will treat them separately for convenience. As in the case of the amplitudes (1) and (2), the amplitude (3) in figure 4 will have a regular field insertion. However, now in addition we must insert the effective nuclear vertex (2.11) for the multiple gluon scatterings. We should integrate over nuclear momentum transfer k_2 to obtain,

$$\begin{aligned} \mathcal{M}_3^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) & \quad (2.19) \\ = \int \frac{d^4 k_2}{(2\pi)^4} \bar{u}(\mathbf{q}) & (-i q_f e \gamma^\mu) S_0(q + k_\gamma) \mathcal{T}(k_2, q + k_\gamma) S_0(q + k_\gamma - k_2) (-i g \not{A}_R(P - k_2) \cdot t) v(\mathbf{p}). \end{aligned}$$

We then integrate over k_2^+ and k_2^- . This integration is trivial for k_2^+ since $\mathcal{T}(k_2, q + k_\gamma)$ contains $\delta(k_2^+)$. Only the proton field part A_p^μ of the regular field gives a finite contribution. In this part, the k_2^- integration is also trivial because A_p^μ contains $\delta(P^- - k_2^-)$. We shall now demonstrate that the integration over the remaining part of A_R^μ vanishes by

the residue theorem. The singularities in k_2^- of the regular field and the quark propagator $S_0(q + k_\gamma - k_2)$, respectively, are

$$\begin{aligned} k_2^- &= P^- - \frac{(\mathbf{P}_\perp - \mathbf{k}_{2\perp})^2}{2P^+} + \frac{i\varepsilon}{2P^+}, & k_2^- &= P^- + i\varepsilon, \\ k_2^- &= q^- + k_\gamma^- - \frac{m^2 + (\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_{2\perp})^2}{2(q^+ + k_\gamma^+)} + \frac{i\varepsilon}{2(q^+ + k_\gamma^+)}, \end{aligned} \quad (2.20)$$

where the first pole comes from the prefactor and the second from C_U^+ in A_R^μ . Since all the three poles are above the real k_2^- axis, the k_2^- integral vanishes by the residue theorem. This result has the clean physical interpretation that the quark-antiquark pair is first created in the proton and subsequently the quark scatters off the gluons in the nucleus. The calculation of the diagrams (4) and (5) is analogous. We can collect the results for the amplitude vector in a compact form as

$$\mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = -q_f e g^2 \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^\alpha(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) R_\beta^\mu(\mathbf{k}_{1\perp}) [\tilde{U}(\mathbf{x}_\perp) - 1] t^a v(\mathbf{p}), \quad (2.21)$$

where the integration variable was changed from k_2 to $k_1 = P - k_2$ and $\beta \in 3, 4, 5$. The symbol $R_\beta^\mu(\mathbf{k}_{1\perp})$ is a shorthand notation for the Dirac structure

$$\begin{aligned} R_3^\mu(\mathbf{k}_{1\perp}) &\equiv \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \gamma^+ \frac{\mathbf{k}_{1\perp} - \mathbf{p}_\perp + m}{2(q^+ + k_\gamma^+)p^- + M^2(\mathbf{k}_{1\perp} - \mathbf{p}_\perp)} \gamma^-, \\ R_4^\mu(\mathbf{k}_{1\perp}) &\equiv -\gamma^+ \frac{\not{q} + \not{\mathbf{k}}_{1\perp} - \not{\mathbf{P}}_\perp + m}{2q^+(p^- + k_\gamma^-) + M^2(\mathbf{k}_{1\perp} - \mathbf{p}_\perp - \mathbf{k}_{\gamma\perp})} \gamma^\mu \frac{\mathbf{k}_{1\perp} - \mathbf{p}_\perp + m}{2(q^+ + k_\gamma^+)p^- + M^2(\mathbf{k}_{1\perp} - \mathbf{p}_\perp)} \gamma^-, \\ R_5^\mu(\mathbf{k}_{1\perp}) &\equiv \gamma^+ \frac{\not{\mathbf{p}}_\perp + \not{\mathbf{k}}_{\gamma\perp} - \not{\mathbf{k}}_{1\perp} - m}{2q^+(p^- + k_\gamma^-) + M^2(\mathbf{k}_{1\perp} - \mathbf{p}_\perp - \mathbf{k}_{\gamma\perp})} \gamma^- \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu, \end{aligned} \quad (2.22)$$

where we define $\not{\mathbf{p}}_\perp \equiv p_i \gamma^i$ and $M^2(\mathbf{p}_\perp) \equiv \mathbf{p}_\perp^2 + m^2$ as the transverse mass. The reductions to transverse Dirac matrices in the numerators comes from using $k_1^+ = P^+$, $k_1^- = 0$ and also the identities $(\gamma^+)^2 = 0$, $(\gamma^-)^2 = 0$.

The next three contributions to the photon amplitude, represented in diagrams (6)–(8) of figure 4, can be found in the same fashion, and as the former, can be shown to have vanishing pole integrations. The amplitudes for these processes are

$$\mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = -q_f e g^2 \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^\alpha(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) R_\beta^\mu(\mathbf{k}_{1\perp}) t^a [\tilde{U}^\dagger(\mathbf{x}_\perp) - 1] v(\mathbf{p}), \quad (2.23)$$

where $\beta \in 6, 7, 8$ corresponds to the respective diagrams in figure 4 and the corresponding Dirac structures

$$\begin{aligned} R_6^\mu(\mathbf{k}_{1\perp}) &\equiv \gamma^- \frac{\not{q}_\perp - \not{\mathbf{k}}_{1\perp} + m}{2(p^+ + k_\gamma^+)q^- + M^2(\mathbf{k}_{1\perp} - \mathbf{q}_\perp)} \gamma^+ \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu, \\ R_7^\mu(\mathbf{k}_{1\perp}) &\equiv -\gamma^- \frac{\not{q} - \not{\mathbf{k}}_{1\perp} + m}{2(p^+ + k_\gamma^+)q^- + M^2(\mathbf{k}_{1\perp} - \mathbf{q}_\perp)} \gamma^\mu \frac{\not{p} + \not{\mathbf{k}}_{1\perp} - \not{\mathbf{P}}_\perp - m}{2p^+(q^- + k_\gamma^-) + M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_{1\perp})} \gamma^+, \\ R_8^\mu(\mathbf{k}_{1\perp}) &\equiv \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \gamma^- \frac{\mathbf{k}_{1\perp} - \not{q}_\perp - \not{\mathbf{k}}_{\gamma\perp} - m}{2p^+(q^- + k_\gamma^-) + M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_{1\perp})} \gamma^+. \end{aligned} \quad (2.24)$$

Figure 5. Regular contributions for the amplitude with two Wilson lines in the fundamental representation.

To tidy up our notation, we will express the sum of the contributions (3)–(8) in figure 4 as

$$\sum_{\beta=3}^8 \mathcal{M}_{\beta}^{\mu}(\mathbf{p}, \mathbf{q}, \mathbf{k}_{\gamma}) = -q_f e g^2 \int_{\mathbf{k}_{\perp} \mathbf{k}_{1\perp}} \int_{\mathbf{x}_{\perp} \mathbf{y}_{\perp}} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{k_{1\perp}^2} e^{i\mathbf{k}_{\perp} \cdot \mathbf{x}_{\perp} + i(\mathbf{P}_{\perp} - \mathbf{k}_{\perp} - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_{\perp}} \quad (2.25)$$

$$\times \bar{u}(\mathbf{q}) \left\{ T_q^{\mu}(\mathbf{k}_{1\perp}) [\tilde{U}(\mathbf{x}_{\perp}) - 1] t^a + T_{\bar{q}}^{\mu}(\mathbf{k}_{1\perp}) t^a [\tilde{U}^{\dagger}(\mathbf{y}_{\perp}) - 1] \right\} v(\mathbf{p}),$$

where the total Dirac structure is combined as

$$T_q^{\mu}(\mathbf{k}_{1\perp}) \equiv \sum_{\beta=3}^5 R_{\beta}^{\mu}(\mathbf{k}_{1\perp}), \quad T_{\bar{q}}^{\mu}(\mathbf{k}_{1\perp}) \equiv \sum_{\beta=6}^8 R_{\beta}^{\mu}(\mathbf{k}_{1\perp}). \quad (2.26)$$

In the first term in (2.25), we introduced a dummy integration over \mathbf{y}_{\perp} and \mathbf{k}_{\perp} . In the second term in (2.25), we renamed $\mathbf{x}_{\perp} \rightarrow \mathbf{y}_{\perp}$ and further, introduced a dummy integration over \mathbf{x}_{\perp} and \mathbf{k}_{\perp} .

Let us now consider the case where there are two insertions of the effective vertex on the quark propagator. The contribution corresponding to a photon emission between two insertions of the effective vanishes for the same kinematic reasons as previously — the pole integration yields a null contribution. Thus the only non-zero contributions come from diagrams where one insertion is on the quark line and the other on the anti-quark line. There are four such contributions, which are listed as diagrams (9)–(12) in figure 5.

All of these diagrams are computed with the same logic as previously. As an example, we focus on diagram (9). The corresponding amplitude can be written as

$$\mathcal{M}_9^{\mu}(\mathbf{p}, \mathbf{q}, \mathbf{k}_{\gamma}) = \int \frac{d^4 k}{(2\pi)^4} \frac{d^4 k_1}{(2\pi)^4} \bar{u}(\mathbf{q}) (-i q_f e \gamma^{\mu}) S_0(q+k_{\gamma}) \mathcal{T}(k, q+k_{\gamma}) S_0(q+k_{\gamma}-k) \quad (2.27)$$

$$\times (-i g \mathbf{A}_R(k_1) \cdot t) S_0(q+k_{\gamma}-k-k_1) \mathcal{T}(P-k-k_1, q+k_{\gamma}-k-k_1) v(\mathbf{p}).$$

As for the case with only one effective vertex, and for the same reasons articulated there, only the proton piece A_p^μ of the regular field A_R^μ contributes. The integrals over k^+ , k_1^+ and k_1^- can be performed thanks to the δ -functions in the two effective vertices \mathcal{T} and in A_p^μ , respectively. The remaining integration over k^- can be evaluated by the method of residues. As in the case of the one effective vertex insertion, the gluon scattering vertices (C_U^μ and C_V^μ) are kinematically forbidden by the pole integration. Performing similar steps for the remaining diagrams (10)–(12), the amplitude of the sum of the diagrams (9)–(12) can be expressed as

$$\sum_{\beta=9}^{12} \mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = -q_f e g^2 \int_{\mathbf{k}_\perp \mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp \mathbf{y}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp} \quad (2.28)$$

$$\times \bar{u}(\mathbf{q}) T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) [\tilde{U}(\mathbf{x}_\perp) - 1] t^a [\tilde{U}^\dagger(\mathbf{y}_\perp) - 1] v(\mathbf{p}),$$

where

$$T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv \sum_{\beta=9}^{12} R_\beta^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}). \quad (2.29)$$

The Dirac structures here for $\beta = 9, \dots, 12$, corresponding to the diagrams (9)–(12) in figure 5, are

$$R_9^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv -\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \gamma^+ \frac{(\not{q}_\perp + \not{k}_{\gamma\perp} - \not{k}_\perp + m) \gamma^- (\not{q}_\perp + \not{k}_{\gamma\perp} - \not{k}_\perp - \not{k}_{1\perp} + m) \gamma^+}{N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp})},$$

$$R_{10}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv \frac{\gamma^+ (\not{q}_\perp - \not{k}_\perp + m) \gamma^- (\not{q}_\perp - \not{k}_\perp - \not{k}_{1\perp} + m)}{N_q(\mathbf{k}_\perp, \mathbf{k}_{1\perp})} \gamma^+ \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu,$$

$$R_{11}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv 2p^+ \frac{\gamma^+ (\not{q} + m - \not{k}_\perp) \gamma^\mu (\not{q}_\perp + \not{k}_{\gamma\perp} - \not{k}_\perp + m) \gamma^- (\not{q}_\perp + \not{k}_{\gamma\perp} - \not{k}_\perp - \not{k}_{1\perp} + m) \gamma^+}{S(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp})}$$

$$- M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \frac{\gamma^+ (\not{q} + m - \not{k}_\perp) \gamma^\mu \gamma^+ \gamma^- (\not{q}_\perp + \not{k}_{\gamma\perp} - \not{k}_\perp - \not{k}_{1\perp} + m) \gamma^+}{S(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp})},$$

$$R_{12}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv 2q^+ \frac{\gamma^+ (\not{q}_\perp - \not{k}_\perp + m) \gamma^- (\not{q}_\perp - \not{k}_{1\perp} - \not{k}_\perp + m) \gamma^\mu (\not{P}_\perp - \not{k}_{1\perp} - \not{k}_\perp - \not{p} + m) \gamma^+}{S(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) N_q(\mathbf{k}_\perp, \mathbf{k}_{1\perp})}$$

$$+ M^2(\mathbf{q}_\perp - \mathbf{k}_\perp) \frac{\gamma^+ (\not{q}_\perp - \not{k}_\perp + m) \gamma^- \gamma^+ \gamma^\mu (\not{P}_\perp - \not{k}_{1\perp} - \not{k}_\perp - \not{p} + m) \gamma^+}{S(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) N_q(\mathbf{k}_\perp, \mathbf{k}_{1\perp})}. \quad (2.30)$$

For clarity of presentation, the following functions in the denominator have been defined as

$$N_q(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv 2(p^+ + k_\gamma^+) M^2(\mathbf{q}_\perp - \mathbf{k}_\perp) + 2q^+ M^2(\mathbf{q}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}),$$

$$N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv 2p^+ M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp) + 2(q^+ + k_\gamma^+) M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp - \mathbf{k}_{1\perp}), \quad (2.31)$$

$$S(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv 4p^+ q^+ k_\gamma^- + 2q^+ M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) + 2p^+ M^2(\mathbf{q}_\perp - \mathbf{k}_\perp).$$

In all the equations presented here, \mathbf{k}_\perp stands for the momentum transferred from the dense nucleus to the quark line. Likewise, $\mathbf{k}_{1\perp}$ is the momentum transferred from the proton. This is transparent since the proton color sources $\rho_p^a(\mathbf{k}_{1\perp})$ are dependent on this integration variable alone. From this fact, and from the fact that the initial momentum flow must be inferred from the final state momenta \mathbf{P}_\perp , one can readily notice that $\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}$ is the momentum transfer from the nucleus to the antiquark.

Figure 6. Singular diagrams of the process. The blob represents the effective vertex defined in eq. (2.11).

2.3 Singular contributions to the amplitude

The terms for which the $q\bar{q}$ is produced by the singular part of the field A_S^μ are represented by the diagrams (S1) and (S2) in figure 6, corresponding to both the creation of the $q\bar{q}$ pair, and the subsequent emission of the photon from within the nucleus. The amplitude for this process is non-vanishing in the Lorenz gauge $\partial_\mu A^\mu = 0$ and needs further explanation. Without regularization, the expressions for amplitudes (S1) and (S2) would look the same as in eq. (2.14), but with the regular field exchanged for the singular field. With regularization, the $\delta(x^+)$ function has a small width: $\delta(x^+) \rightarrow \delta_\varepsilon(x^+)$. This allows the $q\bar{q}$ to undergo multiple gluon scatterings.

Diagrams (S1) and (S2) split into four different parts; each one corresponds to insertions on the quark and the antiquark lines, making four distinct combinations. However these insertions have to be treated differently than in the previous terms we considered as they occur inside the regularized region. This can be achieved by changing the Wilson lines in the insertions into incomplete Wilson lines. Summing all the terms that make up (S1), we find,

$$\begin{aligned} \mathcal{M}_{S1}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) & \quad (2.32) \\ &= \int d^4x e^{iP \cdot x} \bar{u}(\mathbf{q})(-iq_f e\gamma^\mu) S_0(q + k_\gamma) \tilde{U}(\infty, x^+, \mathbf{x}_\perp) (-ig A_S(x) \cdot t) \tilde{U}^\dagger(\infty, x^+, \mathbf{x}_\perp) v(\mathbf{p}). \end{aligned}$$

Several points have to be noted about this expression. Firstly, the structure of the amplitude reflects the fact that for these diagrams the quarks do not rescatter again as a consequence of the vanishing duration of the interaction in the $\varepsilon \rightarrow 0$ limit. In this limit the insertion of the singular field and the rescattering occur in the same transverse plane, which is intuitively what one would expect from a $q\bar{q}$ pair being created and interacting inside a heavily boosted nucleus. Secondly, the photon emission from inside the nucleus or followed by another scattering would be tantamount to resolving the nuclear gluon shock wave; this too is not kinematically viable. Therefore one can only have the addition of an external photon leg emitted by the outgoing quark or antiquark.

Using the identity

$$\tilde{U}(\infty, x^+, \mathbf{x}_\perp) t^a \tilde{U}^\dagger(\infty, x^+, \mathbf{x}_\perp) = t^b U^{ba}(\infty, x^+, \mathbf{x}_\perp), \quad (2.33)$$

and the formula [16]

$$\frac{ig}{2} \int_{-\infty}^{\infty} dx^+ [U(\infty, x^+; \mathbf{x}_\perp) A_A^-(x) \cdot T V(\infty, x^+; \mathbf{x}_\perp)] = U(\mathbf{x}_\perp) - V(\mathbf{x}_\perp), \quad (2.34)$$

we obtain,

$$\begin{aligned} \mathcal{M}_{S1}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -\frac{q_f e g^2}{P^+} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{k_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \{ [U(\mathbf{x}_\perp) - 1] - [V(\mathbf{x}_\perp) - 1] \}^{ba} \\ &\quad \times \bar{u}(\mathbf{q}) \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \gamma^+ t^b v(\mathbf{p}). \end{aligned} \quad (2.35)$$

A similar procedure for (S2) gives

$$\begin{aligned} \mathcal{M}_{S2}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= \frac{q_f e g^2}{P^+} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{k_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \{ [U(\mathbf{x}_\perp) - 1] - [V(\mathbf{x}_\perp) - 1] \}^{ba} \\ &\quad \times \bar{u}(\mathbf{q}) \gamma^+ \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu t^b v(\mathbf{p}). \end{aligned} \quad (2.36)$$

In these expressions, we have added and subtracted the adjoint representation identity matrix to show their similarity to eqs. (2.17) and (2.18). In the following, it will be shown that some of these contributions cancel out.

2.4 Assembling the contributions: the complete result for the photon amplitude

The net contribution to the amplitude is given by a summation of the terms in eqs. (2.17), (2.18), (2.25), (2.28), (2.35) and (2.36). There are several cancellations that occur when we put these terms together. The cancellation of the Wilson line $V(\mathbf{x}_\perp)$ will be addressed first, as it was anticipated, and it stands as a good check of our computation. Firstly, using the relations of eqs. (2.4) and (2.9) $C_{V,\text{reg}}^\mu(P)$ is explicitly written as

$$C_{V,\text{reg}}^\mu(P) = 2P^\mu - \frac{P^2}{P^+} \delta^{\mu-}. \quad (2.37)$$

Using the identities

$$\begin{aligned} \bar{u}(\mathbf{q}) \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \not{p} t^a v(\mathbf{p}) &= \bar{u}(\mathbf{q}) \gamma^\mu t^a v(\mathbf{p}), \\ \bar{u}(\mathbf{q}) \not{p} \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu t^a v(\mathbf{p}) &= \bar{u}(\mathbf{q}) \gamma^\mu t^a v(\mathbf{p}), \end{aligned} \quad (2.38)$$

it follows that the first term of (2.37) cancels out within eqs. (2.17) and (2.18). These relations leave us with only the second term in $C_{V,\text{reg}}^\mu(P)$. It is straightforward to check that both remaining contributions in eqs. (2.17) and (2.18) are the counterparts of the V dependent terms in the singular diagrams, and so eqs. (2.35) and (2.36) demonstrate the anticipated cancellation.

The resulting effective vertex for the U terms in the sum of the diagrams (R1), (S1) and separately (R2), (S2) is

$$\mathcal{C}_U(P, \mathbf{k}_{1\perp}) - \gamma^+ \frac{1}{P^+}, \quad (2.39)$$

which can equivalently be written as

$$\mathcal{C}_U(P, \mathbf{k}_{1\perp}) + \frac{1}{2}\mathcal{C}_V(P) = \mathcal{C}_L(P, \mathbf{k}_{1\perp}), \quad (2.40)$$

where the expression C_L^μ is the Lipatov effective vertex

$$C_L^+(q, \mathbf{k}_{1\perp}) = q^+ - \frac{\mathbf{k}_{1\perp}^2}{q^- + i\epsilon}, \quad C_L^-(q, \mathbf{k}_{1\perp}) = \frac{(\mathbf{q}_\perp - \mathbf{k}_{1\perp})^2}{q^+} - q^-, \quad C_{L\perp}(q, \mathbf{k}_{1\perp}) = \mathbf{q}_\perp - 2\mathbf{k}_{1\perp}. \quad (2.41)$$

The terms that survive the above mentioned cancellation give the net amplitude for a gluon to first scatter off the nucleus before emitting a $q\bar{q}$ pair and can be expressed as

$$\begin{aligned} \mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &\equiv \mathcal{M}_{R\beta}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) + \mathcal{M}_{S\beta}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) \\ &= -q_f e g^2 \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^\alpha(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) [U(\mathbf{x}_\perp) - 1]^{ba} t^b R_\beta^\mu(\mathbf{k}_{1\perp}) v(\mathbf{p}), \end{aligned} \quad (2.42)$$

with $\beta = 1, 2$ and where

$$\begin{aligned} R_1^\mu(\mathbf{k}_{1\perp}) &\equiv -\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \frac{\mathcal{C}_L(P, \mathbf{k}_{1\perp})}{P^2}, \\ R_2^\mu(\mathbf{k}_{1\perp}) &\equiv \frac{\mathcal{C}_L(P, \mathbf{k}_{1\perp})}{P^2} \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu. \end{aligned} \quad (2.43)$$

Combining all the results, the full amplitude vector is

$$\begin{aligned} \mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= \sum_{\beta=1}^{12} \mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) \\ &= -q_f e g^2 \int_{\mathbf{k}_\perp, \mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp, \mathbf{y}_\perp} \frac{\rho_p^\alpha(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp} \\ &\quad \times \bar{u}(\mathbf{q}) \left\{ T_g^\mu(\mathbf{k}_{1\perp}) [U(\mathbf{x}_\perp) - 1]^{ba} t^b + T_q^\mu(\mathbf{k}_{1\perp}) [\tilde{U}(\mathbf{x}_\perp) - 1] t^a \right. \\ &\quad \left. + T_{\bar{q}}^\mu(\mathbf{k}_{1\perp}) t^a [\tilde{U}^\dagger(\mathbf{y}_\perp) - 1] + T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) [\tilde{U}(\mathbf{x}_\perp) - 1] t^a [\tilde{U}^\dagger(\mathbf{y}_\perp) - 1] \right\}, \end{aligned} \quad (2.44)$$

with

$$T_g^\mu(\mathbf{k}_{1\perp}) \equiv \sum_{\beta=1}^2 R_\beta^\mu(\mathbf{k}_{1\perp}). \quad (2.45)$$

This last expression extends the Dirac structure found in ref. [16] to photon production. We note that in eq. (2.44) we introduced a dummy integration over \mathbf{x}_\perp , \mathbf{y}_\perp and \mathbf{k}_\perp to ensure that all the terms have identical integration variables.

The result (2.44) can be further simplified by making use of the identities,

$$\begin{aligned} T_g^\mu(\mathbf{P}_\perp) + T_q^\mu(\mathbf{P}_\perp) + T_{\bar{q}}^\mu(\mathbf{P}_\perp) - T_{q\bar{q}}^\mu(\mathbf{0}, \mathbf{P}_\perp) &= 0, \\ T_q^\mu(\mathbf{P}_\perp - \mathbf{k}_\perp) - T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{P}_\perp - \mathbf{k}_\perp) &= 0, \quad T_q^\mu(\mathbf{k}_{1\perp}) - T_{q\bar{q}}^\mu(\mathbf{0}, \mathbf{k}_{1\perp}) = 0. \end{aligned} \quad (2.46)$$

Using eq. (2.46), the expression for the amplitude can considerably simplify to

$$\begin{aligned} \mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = & -q_f e g^2 \int_{\mathbf{k}_\perp \mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp \mathbf{y}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp} \\ & \times \bar{u}(\mathbf{q}) \{ T_g^\mu(\mathbf{k}_{1\perp}) U(\mathbf{x}_\perp)^{ba} t^b + T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) \} v(\mathbf{p}). \end{aligned} \quad (2.47)$$

This expression for the photon amplitude is a key result of this work. In A, we will show that this expression for the amplitude in Lorenz gauge is identical to the expression derived in light-cone gauge.

Before we conclude this section, we wish to make a few points regarding the final result. Firstly, in eq. (2.46), the sum of the four effective vertices is zero as a consequence of momentum conservation. If there is no nuclear and proton momentum transfer, the quark-antiquark dipole cannot be created. The second and third relations in eq. (2.46) stand for the vanishing of contributions if there is no momentum transfer either from the projectile or the target. We are thus left only with contributions to the photon amplitude that have i) both the quark and the antiquark interact with the nucleus after being created (and before or after radiating the photon), and those ii) where the gluon from the proton scatters off the nucleus before creating the quark-antiquark pair and thence, the photon.

3 The inclusive photon cross section

The probability for creating a $q\bar{q}$ pair with 4-momenta q and p , respectively, and a photon with momentum k_γ , for a fixed distribution of sources ρ_p in the projectile and ρ_A in the target, respectively, is given by

$$P_{\text{incl.}}^\gamma[\rho_p, \rho_A] = \int \frac{d^3\mathbf{p}}{(2\pi)^3 2E_p} \frac{d^3\mathbf{q}}{(2\pi)^3 2E_q} \frac{d^3\mathbf{k}_\gamma}{(2\pi)^3 2E_{k_\gamma}} \sum_\lambda \sum_{\text{spin}} |\mathcal{M}_\lambda(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma)|^2. \quad (3.1)$$

Here E_p , E_q and E_{k_γ} denote the relativistic energies of the antiquark, quark and photon, respectively. The sum over polarizations can be taken by noting that

$$\sum_\lambda |\mathcal{M}_\lambda(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma)|^2 = \sum_\lambda \epsilon_\mu(\mathbf{k}_\gamma, \lambda) \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) \mathcal{M}^{\mu*}(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma). \quad (3.2)$$

The color average of an inclusive quantity \mathcal{O} must be taken after taking the modulus squared of the amplitude [15],

$$\langle \mathcal{O} \rangle = \int \mathcal{D}\rho_p \mathcal{D}\rho_A W_p[\rho_p] W_A[\rho_A] \mathcal{O}[\rho_p, \rho_A]. \quad (3.3)$$

The weight functionals $W_p[\rho_p]$ and $W_A[\rho_A]$ are density matrices that obey the JIMWLK evolution equations [32–35] that describe the renormalization group evolution of distributions of color charges in the wave-functions of the projectile and the target, respectively, from their respective fragmentation regions at large x down to the small x values probed by measurements in high energy collisions.

Thus the impact parameter-dependent triple differential probability corresponding to the probability functional defined above is

$$\frac{dP^\gamma(\mathbf{b}_\perp)}{d^6K_\perp d^3\eta_K} = \frac{1}{8(2\pi)^9} \sum_\lambda \sum_{\text{spin}} \left\langle |\mathcal{M}_\lambda(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma)|^2 \right\rangle, \quad (3.4)$$

where $d^6K_\perp \equiv d^2\mathbf{p}_\perp d^2\mathbf{q}_\perp d^2\mathbf{k}_{\gamma\perp}$ and $d^3\eta_K \equiv d\eta_p d\eta_q d\eta_{k_\gamma}$. The angle brackets, $\langle \dots \rangle$, represent the color average in eq. (3.3). The triple-differential inclusive cross section can be obtained by integrating the above expression over impact parameter \mathbf{b}_\perp ,

$$\frac{d\sigma^\gamma}{d^6K_\perp d^3\eta_K} = \int_{\mathbf{b}_\perp} \frac{dP^\gamma(\mathbf{b}_\perp)}{d^6K_\perp d^3\eta_K}. \quad (3.5)$$

Using eqs. (2.47) and (3.4), the triple differential probability can be expressed as

$$\begin{aligned} & \frac{dP^\gamma(\mathbf{b}_\perp)}{d^6K_\perp d^3\eta_K} \\ &= \frac{q_f^2 e^2 g^4}{8(2\pi)^9} \int_{\mathbf{k}_\perp \mathbf{k}'_\perp \mathbf{k}_{1\perp} \mathbf{k}'_{1\perp}} \int_{\mathbf{x}_\perp \mathbf{x}'_\perp \mathbf{y}_\perp \mathbf{y}'_\perp} e^{i(\mathbf{k}_\perp \cdot \mathbf{x}_\perp - \mathbf{k}'_\perp \cdot \mathbf{x}'_\perp) + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp - i(\mathbf{P}_\perp - \mathbf{k}'_\perp - \mathbf{k}'_{1\perp}) \cdot \mathbf{y}'_\perp} \\ & \times \frac{\left\langle \rho_p^a(\mathbf{k}_{1\perp}) \rho_p^{\dagger a'}(\mathbf{k}'_{1\perp}) \right\rangle}{\mathbf{k}_{1\perp}^2 \mathbf{k}'_{1\perp}{}^2} \left\{ \tau_{g,g}(\mathbf{k}_{1\perp}; \mathbf{k}'_{1\perp}) \text{tr}_c \langle t^b U^{ba}(\mathbf{x}_\perp) t^{b'} U^{\dagger a' b'}(\mathbf{x}'_\perp) \rangle \right. \\ & + \tau_{q\bar{q},g}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}; \mathbf{k}'_\perp, \mathbf{k}'_{1\perp}) \text{tr}_c \langle \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) t^{b'} U^{\dagger a' b'}(\mathbf{x}'_\perp) \rangle \\ & + \tau_{g,q\bar{q}}(\mathbf{k}_{1\perp}; \mathbf{k}_\perp, \mathbf{k}'_{1\perp}, \mathbf{k}'_\perp) \text{tr}_c \langle t^b U^{ba} \tilde{U}(\mathbf{y}'_\perp) t^{a'} \tilde{U}^\dagger(\mathbf{x}'_\perp) \rangle \\ & \left. + \tau_{q\bar{q},q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}; \mathbf{k}'_\perp, \mathbf{k}'_{1\perp}) \text{tr}_c \langle \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) \tilde{U}(\mathbf{y}'_\perp) t^{a'} \tilde{U}^\dagger(\mathbf{x}'_\perp) \rangle \right\}, \quad (3.6) \end{aligned}$$

where we wrote four Dirac traces in a compact form using the following notation,

$$\tau_{n,m} \equiv \text{tr}[(\not{q} + m) T_n^\mu (m - \not{p}) \gamma^0 T_{m,\mu}^\dagger \gamma^0], \quad (3.7)$$

with $n, m \in \{g, q\bar{q}\}$ and where we used the abbreviations $T_g^\mu \equiv T_g^\mu(\mathbf{k}_{1\perp})$, $T_g'^\mu \equiv T_g^\mu(\mathbf{k}'_{1\perp})$ and $T_{q\bar{q}}^\mu \equiv T_{q\bar{q}}^\mu(\mathbf{k}_{1\perp}, \mathbf{k}_\perp)$, $T_{q\bar{q}}'^\mu \equiv T_{q\bar{q}}^\mu(\mathbf{k}'_{1\perp}, \mathbf{k}'_\perp)$.

We will now shift the spatial transverse coordinates by the impact parameter to make them relative to the center of the nucleus,

$$\{\mathbf{x}_\perp, \mathbf{x}'_\perp, \mathbf{y}_\perp, \mathbf{y}'_\perp\} \rightarrow \{\mathbf{x}_\perp - \mathbf{b}_\perp, \mathbf{x}'_\perp - \mathbf{b}_\perp, \mathbf{y}_\perp - \mathbf{b}_\perp, \mathbf{y}'_\perp - \mathbf{b}_\perp\}. \quad (3.8)$$

Since the Wilson line correlators are approximately translational invariant for a large nucleus, the phases in the integrand yield a factor of $e^{i\mathbf{b}_\perp \cdot (\mathbf{k}_{1\perp} - \mathbf{k}'_{1\perp})}$ after the above coordinate shift. Thus, to obtain the triple-differential cross section we can easily integrate over the impact parameter \mathbf{b}_\perp , resulting in a δ -function: $(2\pi)^2 \delta^{(2)}(\mathbf{k}'_{1\perp} - \mathbf{k}_{1\perp})$. In eq. (3.6), we also introduce a dummy integration over $\mathbf{k}_{2\perp}$, together with a δ -function representing overall momentum conservation $(2\pi)^2 \delta^{(2)}(\mathbf{P}_\perp - \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp})$.

As discussed previously in refs. [15, 16], the color averages in the formula above can be re-expressed in terms of novel unintegrated distribution functions. The correlator of color sources in the projectile proton is defined to be

$$\langle \rho_p^a(\mathbf{k}_{1\perp}) \rho_p^{\dagger b}(\mathbf{k}'_{1\perp}) \rangle = \frac{\delta^{ab}}{2\pi N_c C_F g^2} \left(\frac{\mathbf{k}_{1\perp} + \mathbf{k}'_{1\perp}}{2} \right)^2 \int_{\mathbf{r}_\perp} e^{i(\mathbf{k}_{1\perp} - \mathbf{k}'_{1\perp}) \cdot \mathbf{r}_\perp} \frac{d\varphi_p(\frac{1}{2}(\mathbf{k}_{1\perp} + \mathbf{k}'_{1\perp})|\mathbf{r}_\perp)}{d^2\mathbf{r}_\perp}, \quad (3.9)$$

where $d\varphi_p/d^2\mathbf{r}_\perp$ is the proton unintegrated gluon distribution per unit area, \mathbf{r}_\perp is the variable that runs over the transverse profile of the proton, $C_F \equiv (N_c^2 - 1)/2N_c$ is the $SU(N_c)$ quadratic Casimir in the fundamental representation. When the momenta in the argument of $d\varphi_p/d^2\mathbf{r}_\perp$ are identical as is the case after the integration over \mathbf{b}_\perp , the expression greatly simplifies to

$$\langle \rho_p^a(\mathbf{k}_{1\perp}) \rho_p^{\dagger b}(\mathbf{k}_{1\perp}) \rangle = \frac{\delta^{ab} \mathbf{k}_{1\perp}^2}{2\pi N_c C_F g^2} \varphi_p(\mathbf{k}_{1\perp}, Y_p), \quad (3.10)$$

with $\varphi_p(\mathbf{k}_{1\perp}, Y_p)$ being the unintegrated gluon distribution in the proton. In line with the dilute-dense expansion performed here to $O(\rho_p^1)$, $\varphi_p(\mathbf{k}_{1\perp})$ will evolve according to the BFKL equation.

The identification of the correlator of color sources can be straightforwardly generalized to correlators of Wilson lines which likewise can be expressed in terms of nuclear unintegrated distribution functions [16, 36, 37]. In conventional pQCD language, these unintegrated momentum distributions resum a sub-class of all twist correlations in the nucleus. The correlator of two adjoint Wilson lines can be expressed as

$$\begin{aligned} & \int_{\mathbf{k}_\perp \mathbf{k}'_\perp} \int_{\mathbf{x}_\perp \mathbf{x}'_\perp \mathbf{y}_\perp \mathbf{y}'_\perp} e^{i(\mathbf{k}_\perp \cdot \mathbf{x}_\perp - \mathbf{k}'_\perp \cdot \mathbf{x}'_\perp) + i(\mathbf{k}_{2\perp} - \mathbf{k}_\perp) \cdot \mathbf{y}_\perp - i(\mathbf{k}_{2\perp} - \mathbf{k}'_\perp) \cdot \mathbf{y}'_\perp} \delta^{aa'} \text{tr}_c \langle t^b U^{ba}(\mathbf{x}_\perp) t^{b'} U^{\dagger a' b'}(\mathbf{x}'_\perp) \rangle \\ & \equiv \frac{2N_c \alpha_S}{\mathbf{k}_{2\perp}^2} \phi_A^{g,g}(\mathbf{k}_{2\perp}). \end{aligned} \quad (3.11)$$

Similarly, the three point fundamental-adjoint Wilson line correlator can be expressed as

$$\begin{aligned} & \int_{\mathbf{k}'_\perp} \int_{\mathbf{x}_\perp \mathbf{x}'_\perp \mathbf{y}_\perp \mathbf{y}'_\perp} e^{i(\mathbf{k}_\perp \cdot \mathbf{x}_\perp - \mathbf{k}'_\perp \cdot \mathbf{x}'_\perp) + i(\mathbf{k}_{2\perp} - \mathbf{k}_\perp) \cdot \mathbf{y}_\perp - i(\mathbf{k}_{2\perp} - \mathbf{k}'_\perp) \cdot \mathbf{y}'_\perp} \delta^{aa'} \text{tr}_c \langle \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) t^{b'} U^{\dagger a' b'}(\mathbf{x}'_\perp) \rangle \\ & \equiv \frac{2N_c \alpha_S}{\mathbf{k}_{2\perp}^2} \phi_A^{q\bar{q},g}(\mathbf{k}_\perp, \mathbf{k}_{2\perp} - \mathbf{k}_\perp; \mathbf{k}_{2\perp}), \end{aligned} \quad (3.12)$$

and likewise for its Hermitean conjugate expression in the cross section. Finally, the four point correlator of fundamental Wilson lines can be expressed as

$$\begin{aligned} & \int_{\mathbf{x}_\perp \mathbf{x}'_\perp \mathbf{y}_\perp \mathbf{y}'_\perp} e^{i(\mathbf{k}_\perp \cdot \mathbf{x}_\perp - \mathbf{k}'_\perp \cdot \mathbf{x}'_\perp) + i(\mathbf{k}_{2\perp} - \mathbf{k}_\perp) \cdot \mathbf{y}_\perp - i(\mathbf{k}_{2\perp} - \mathbf{k}'_\perp) \cdot \mathbf{y}'_\perp} \delta^{aa'} \text{tr}_c \langle \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) \tilde{U}(\mathbf{y}'_\perp) t^{a'} \tilde{U}^\dagger(\mathbf{x}'_\perp) \rangle \\ & \equiv \frac{2N_c \alpha_S}{\mathbf{k}_{2\perp}^2} \phi_A^{q\bar{q},q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{2\perp} - \mathbf{k}_\perp; \mathbf{k}'_\perp, \mathbf{k}_{2\perp} - \mathbf{k}'_\perp). \end{aligned} \quad (3.13)$$

The correlators can be evaluated for a large nuclei with Gaussian random color sources [38–40] that satisfy the relation,

$$\langle \rho_A^a(\mathbf{x}_\perp) \rho_A^b(\mathbf{y}_\perp) \rangle = \delta^{ab} \delta^{(2)}(\mathbf{x}_\perp - \mathbf{y}_\perp) \mu_A^2, \quad (3.14)$$

where the color charge squared per unit area is $\mu_A^2 = A/(2\pi R^2) \sim A^{1/3}$. In general, the correlations amongst color sources in the nuclear wave-function is given by the weight

functional $W_A[\rho_A]$, which as we noted previously, satisfies the JIMWLK equation. This equation is formally equivalent to the Balitsky-JIMWLK hierarchy [41, 42] of n -point Wilson line correlators. The JIMWLK equation has been solved numerically [43, 44]. It was found, to a good approximation, that the solution is well represented by a non-local Gaussian [44], with $\mu_A^2 \rightarrow \mu_A^2(Y_A, \mathbf{x}_\perp)$, with which we can define,

$$\phi_A(Y_A, \mathbf{k}_\perp) = \frac{2\pi N_c C_F g^2}{\mathbf{k}_\perp^2} \int_{\mathbf{x}_\perp} \mu_A^2(Y_A, \mathbf{x}_\perp), \quad (3.15)$$

such that $\phi_A(Y_A, \mathbf{k}_\perp)$ obeys the Balitsky-Kovchegov (BK) equation [41, 45]. In this expression, Y_A is the rapidity, relative to the nuclear beam rapidity, of gluons from the target off which the $q\bar{q}$ pair scatters. The BK equation, for large N_c , is the closed form equation for the “dipole” correlator of Wilson lines — the lowest term in the Balitsky-JIMWLK hierarchy. In the low density limit the BK equation goes to the BFKL equation. Even though the BK equation has a closed form, it cannot be solved analytically. It can however be solved numerically; we will return to this discussion when we later outline the necessary ingredients for the numerical solution of eq. (3.17).

Returning to the triple-differential cross section, with the help of the relations eq. (3.8)–(3.13), we express its final form as

$$\begin{aligned} & \frac{d\sigma^\gamma}{d^6K_\perp d^3\eta_K} \\ &= \frac{\alpha_e \alpha_S^2 q_f^2}{256\pi^8 C_F} \int_{\mathbf{k}_{1\perp} \mathbf{k}_{2\perp}} (2\pi)^2 \delta^{(2)}(\mathbf{P}_\perp - \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp}) \frac{\varphi_p(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2 \mathbf{k}_{2\perp}^2} \\ & \times \left\{ \tau_{g,g}(\mathbf{k}_{1\perp}; \mathbf{k}_{1\perp}) \phi_A^{g,g}(\mathbf{k}_{2\perp}) + \int_{\mathbf{k}_\perp} 2\text{Re}[\tau_{g,q\bar{q}}(\mathbf{k}_{1\perp}; \mathbf{k}_\perp, \mathbf{k}_{1\perp})] \phi_A^{q\bar{q},g}(\mathbf{k}_\perp, \mathbf{k}_{2\perp} - \mathbf{k}_\perp; \mathbf{k}_{2\perp}) \right. \\ & \left. + \int_{\mathbf{k}_\perp \mathbf{k}'_\perp} \tau_{q\bar{q},q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}; \mathbf{k}'_\perp, \mathbf{k}_{1\perp}) \phi_A^{q\bar{q},q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{2\perp} - \mathbf{k}_\perp; \mathbf{k}'_\perp, \mathbf{k}_{2\perp} - \mathbf{k}'_\perp) \right\}. \quad (3.16) \end{aligned}$$

We remind the reader that $\mathbf{P}_\perp = \mathbf{p}_\perp + \mathbf{q}_\perp + \mathbf{k}_{\gamma\perp}$. It is worth noting that the r.h.s. dependence on the external momenta lies only in the overall δ -function and in the Dirac traces.

The expression in eq. (3.16) would be useful if it were feasible to measure direct photons in coincidence with a quarkonium state, for instance the J/Ψ meson. Alternately, by integrating over either the quark (antiquark), this cross section would provide the rate for direct photons measured in coincidence with open charm (anticharm) states. These measurements are challenging even at LHC energies. On the other hand, inclusive prompt photon differential cross section has already been measured at RHIC in deuteron-gold collisions [46, 47] and photon measurements can be anticipated at both RHIC and LHC in p+A collisions in the near future.

The simplest quantity that can be measured is the inclusive prompt-photon single-differential cross section. For this one must integrate over the quark and the antiquark

momenta and rapidities, and one obtains,

$$\begin{aligned}
& \frac{d\sigma^\gamma}{d^2\mathbf{k}_{\gamma\perp} d\eta_{k_\gamma}} \\
&= \frac{\alpha_e \alpha_S^2 q_f^2}{16\pi^4 C_F} \int_0^\infty \frac{dq^+}{q^+} \frac{dp^+}{p^+} \int_{\mathbf{k}_{1\perp} \mathbf{k}_{2\perp} \mathbf{q}_{\perp} \mathbf{p}_{\perp}} (2\pi)^2 \delta^{(2)}(\mathbf{P}_{\perp} - \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp}) \frac{\varphi_p(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2 \mathbf{k}_{2\perp}^2} \\
&\quad \times \left\{ \tau_{g,g}(\mathbf{k}_{1\perp}; \mathbf{k}_{1\perp}) \phi_A^{g,g}(\mathbf{k}_{2\perp}) + \int_{\mathbf{k}_{\perp}} 2\text{Re}[\tau_{g,q\bar{q}}(\mathbf{k}_{1\perp}; \mathbf{k}_{\perp}, \mathbf{k}_{1\perp})] \phi_A^{q\bar{q},g}(\mathbf{k}_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}_{\perp}; \mathbf{k}_{2\perp}) \right. \\
&\quad \left. + \int_{\mathbf{k}_{\perp} \mathbf{k}'_{\perp}} \tau_{q\bar{q},q\bar{q}}(\mathbf{k}_{\perp}, \mathbf{k}_{1\perp}; \mathbf{k}'_{\perp}, \mathbf{k}_{1\perp}) \phi_A^{q\bar{q},q\bar{q}}(\mathbf{k}_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}_{\perp}; \mathbf{k}'_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}'_{\perp}) \right\}. \quad (3.17)
\end{aligned}$$

This expression is the main result of this paper. In the previous related work on quark-antiquark production [16, 37], the integration over the momentum of the quark or the antiquark enabled one to simplify the result so that it depended only on the $\phi_A^{g,g}$ and $\phi_A^{q\bar{q},g}$ nuclear distributions. Unfortunately, it appears no such simplification is possible here due to the particular momentum dependence of the $\tau_{n,m}$ functions. Equation (3.17), however, simplifies considerably in the \mathbf{k}_{\perp} factorization and collinear pQCD limits, which will be the subject of the next section.

4 \mathbf{k}_{\perp} factorization and collinear factorization limits

Our master expression, eq. (3.17), can be simplified considerably in a high transverse momentum expansion of the nuclear unintegrated distributions. The high momentum expansion corresponds to expanding the Wilson lines, $\tilde{U}(\mathbf{x}_{\perp})$ and $U(\mathbf{x}_{\perp})$ in the fundamental and the adjoint representations, to lowest non-trivial order in terms of ρ_A/∇_{\perp}^2 . This is equivalent to the leading twist expansion in pQCD as will become manifest when we consider the collinear factorization limit of our expressions. Physically, this limit corresponds to the dynamics when the density of color sources is large enough to be represented as classical color charges, but only one of the color charges in this classical color distribution is resolved by a high transverse momentum probe. Keeping only the leading-twist terms in the expansion of the Wilson lines in eq. (3.13), one can straightforwardly show that [16, 37]

$$\begin{aligned}
\phi_A^{q\bar{q},q\bar{q}}(Y_A, \mathbf{k}_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}_{\perp}; \mathbf{k}'_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}'_{\perp}) &= (2\pi)^4 \varphi_A(Y_A, \mathbf{k}_{2\perp}) \left\{ \frac{C_F}{N_c} \left[\delta^{(2)}(\mathbf{k}_{\perp}) \delta^{(2)}(\mathbf{k}'_{\perp}) \right. \right. \\
&\quad \left. \left. + \delta^{(2)}(\mathbf{k}_{2\perp} - \mathbf{k}_{\perp}) \delta^{(2)}(\mathbf{k}_{2\perp} - \mathbf{k}'_{\perp}) \right] + \frac{1}{2N_c^2} \left[\delta^{(2)}(\mathbf{k}_{\perp}) \delta^{(2)}(\mathbf{k}_{2\perp} - \mathbf{k}'_{\perp}) + \delta^{(2)}(\mathbf{k}_{2\perp} - \mathbf{k}_{\perp}) \delta^{(2)}(\mathbf{k}'_{\perp}) \right] \right\}. \quad (4.1)
\end{aligned}$$

Similarly,

$$\phi_A^{q\bar{q},g}(Y_A, \mathbf{k}_{\perp}, \mathbf{k}_{2\perp} - \mathbf{k}_{\perp}; \mathbf{k}_{2\perp}) = \frac{1}{2} (2\pi)^2 \varphi_A(Y_A, \mathbf{k}_{2\perp}) \left[\delta^{(2)}(\mathbf{k}_{\perp}) + \delta^{(2)}(\mathbf{k}_{2\perp} - \mathbf{k}_{\perp}) \right], \quad (4.2)$$

and

$$\phi_A^{g,g}(Y_A, \mathbf{k}_{2\perp}) = \varphi_A(Y_A, \mathbf{k}_{2\perp}), \quad (4.3)$$

In complete analogy with (3.10) we have defined

$$\langle \rho_A^a(\mathbf{k}_{2\perp}) \rho_A^{\dagger b}(\mathbf{k}_{2\perp}) \rangle \equiv \frac{\delta^{ab} \mathbf{k}_{2\perp}^2}{2\pi N_c C_F g^2} \varphi_A(Y_A, \mathbf{k}_{2\perp}), \quad (4.4)$$

where the Y_A dependence is now shown explicitly. The unintegrated gluon distribution in the nuclei $\varphi_A(Y_A, \mathbf{k}_{2\perp})$ evolves at this level of approximations according to the BFKL equation.

Substituting these leading twist distributions into eq. (3.17), we find that the cross section simplifies greatly and can be expressed as

$$\frac{d\sigma^\gamma}{d^6 K_\perp d^3 \eta_K} = \frac{\alpha_e \alpha_S^2 q_f^2}{256\pi^8 N_c (N_c^2 - 1)} \int_{\mathbf{k}_{1\perp} \mathbf{k}_{2\perp}} (2\pi)^2 \delta^{(2)}(\mathbf{P}_\perp - \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp}) \times \frac{\varphi_p(Y_p, \mathbf{k}_{1\perp}) \varphi_A(Y_A, \mathbf{k}_{2\perp})}{\mathbf{k}_{1\perp}^2 \mathbf{k}_{2\perp}^2} \Theta(\mathbf{k}_{1\perp}, \mathbf{k}_{2\perp}), \quad (4.5)$$

with

$$\begin{aligned} \Theta(\mathbf{k}_{1\perp}, \mathbf{k}_{2\perp}) & \quad (4.6) \\ & \equiv N_c^2 \text{tr} \left\{ (\not{q} + m) [T_g^\mu(\mathbf{k}_{1\perp}) + T_q^\mu(\mathbf{P}_\perp - \mathbf{k}_{2\perp})] (m - \not{p}) \gamma^0 [T_{g,\mu}(\mathbf{k}_{1\perp}) + T_{q,\mu}(\mathbf{P}_\perp - \mathbf{k}_{2\perp})]^\dagger \gamma^0 \right\} \\ & \quad + N_c^2 \text{tr} \left\{ (\not{q} + m) [T_g^\mu(\mathbf{k}_{1\perp}) + T_{\bar{q}}^\mu(\mathbf{k}_{1\perp})] (m - \not{p}) \gamma^0 [T_{g,\mu}(\mathbf{k}_{1\perp}) + T_{\bar{q},\mu}(\mathbf{k}_{1\perp})]^\dagger \gamma^0 \right\} \\ & \quad - \text{tr} \left\{ (\not{q} + m) [T_q^\mu(\mathbf{P}_\perp - \mathbf{k}_{2\perp}) - T_{\bar{q}}^\mu(\mathbf{k}_{1\perp})] (m - \not{p}) \gamma^0 [T_{q,\mu}(\mathbf{P}_\perp - \mathbf{k}_{2\perp}) - T_{\bar{q},\mu}(\mathbf{k}_{1\perp})]^\dagger \gamma^0 \right\}. \end{aligned}$$

The expression in eq. (4.5) is the \mathbf{k}_\perp factorized expression for inclusive photon production in high energy QCD and is analogous to similar expressions derived previously for gluon production [15, 30, 48] and $q\bar{q}$ pair production [16] in this framework. To derive eq. (4.6) we have taken advantage of the second line in the eq. (2.46) to express $T_{q\bar{q}}^\mu$ in terms of T_q^μ or $T_{\bar{q}}^\mu$.

Alternately, it is useful to arrive at the results in eqs. (4.5) and (4.6) starting directly from the perturbative computation of the amplitude. The leading twist diagrams are listed in figure 7. In fact, the leading twist amplitude in Lorenz gauge can immediately be read off from the original amplitudes (1)–(8) by expanding the Wilson lines to the first non-trivial order. In this case, it gives a non-zero contribution to the amplitude at the order $O(\rho_p^1 \rho_A^1)$. The amplitudes (9)–(12) contain two insertions of the effective vertex (see eq. (2.11)), and so they do not contribute at the order $O(\rho_p^1 \rho_A^1)$. We can then write the leading twist amplitude as

$$\begin{aligned} \mathcal{M}_{\text{LT}}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) & \quad (4.7) \\ & = \int \frac{d^4 k_1}{(2\pi)^4} \int \frac{d^4 k_2}{(2\pi)^4} (2\pi)^4 \delta^{(4)}(P - k_1 - k_2) A_{p,\nu_1}^a(k_1) A_{A,\nu_2}^b(k_2) m_{ab}^{\mu\nu_1\nu_2}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma), \end{aligned}$$

where the gluon fields are given by Fourier transforms of the expressions in eqs. (2.3) and (2.7) and

$$m_{ab}^{\mu\nu_1\nu_2}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = \sum_{\beta=1}^8 m_{\beta,ab}^{\mu\nu_1\nu_2}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma), \quad (4.8)$$

Figure 7. Leading twist reduction and corresponding diagrams. The upper and lower bold lines correspond to the nuclear and proton sources, respectively. In diagrams LT1 and LT2, the blob represents the Lipatov effective vertex.

with the index $\beta = 1, \dots, 8$ corresponding to the respective diagram in figure 7 as

$$\begin{aligned}
 m_{1,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= q_f e g^2 \bar{u}(\mathbf{q}) \gamma^\mu S_0(q + k_\gamma) [t_b, t_a] \frac{\Phi_L(P, k_1)}{P^2} v(\mathbf{p}), \\
 m_{2,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= q_f e g^2 \bar{u}(\mathbf{q}) [t_b, t_a] \frac{\Phi_L(P, k_1)}{P^2} S_0(-p - k_\gamma) \gamma^\mu v(\mathbf{p}), \\
 m_{3,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^\mu S_0(q + k_\gamma) \gamma^+ t_b S_0(k_1 - p) \gamma^- t_a v(\mathbf{p}), \\
 m_{4,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^+ t_b S_0(q - k_2) \gamma^\mu S_0(k_1 - p) \gamma^- t_a v(\mathbf{p}), \\
 m_{5,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^+ t_b S_0(q - k_2) \gamma^- S_0(-p - k_\gamma) \gamma^\mu t_a v(\mathbf{p}), \\
 m_{6,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^- t_a S_0(q - k_1) \gamma^+ t_b S_0(-p - k_\gamma) \gamma^\mu v(\mathbf{p}), \\
 m_{7,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^- t_a S_0(q - k_1) \gamma^\mu S_0(k_2 - p) \gamma^+ t_b v(\mathbf{p}), \\
 m_{8,ab}^{\mu-+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= -i q_f e g^2 \bar{u}(\mathbf{q}) \gamma^\mu S_0(q + k_\gamma) \gamma^- t_a S_0(k_2 - p) \gamma^+ t_b v(\mathbf{p}).
 \end{aligned} \tag{4.9}$$

Inserting the gluon fields from eqs. (2.3) and (2.7), we can perform the light-cone integrations to obtain

$$\begin{aligned}
 \mathcal{M}_{\text{LT}}^\mu &= -i q_f e g^2 \int_{\mathbf{k}_{1\perp} \mathbf{k}_{2\perp}} (2\pi)^2 \delta^{(2)}(\mathbf{P}_\perp - \mathbf{k}_{1\perp} - \mathbf{k}_{2\perp}) \frac{\rho_p^a(\mathbf{k}_{1\perp}) \rho_A^b(\mathbf{k}_{2\perp})}{k_{1\perp}^2 k_{2\perp}^2} \\
 &\quad \times \bar{u}(\mathbf{q}) \left[T_g^\mu(\mathbf{k}_{1\perp}) [t_b, t_a] + T_q^\mu(\mathbf{k}_{1\perp}) t_b t_a - T_{\bar{q}}^\mu(\mathbf{k}_{1\perp}) t_a t_b \right] v(\mathbf{p}),
 \end{aligned} \tag{4.10}$$

By taking the modulus squared and by performing the color averages as in eqs. (3.10) and (4.4), we can confirm that eq. (4.5) is reproduced.

The expression for the amplitude in eq. (4.10), and in particular the individual contributions (4.9), can be compared to the amplitude for prompt photon hadroproduction first computed by Baranov et al. [17] and to the Z^0 hadroproduction from gluon fusion derived recently by Motyka et al. [18]. We have checked that our leading twist k_\perp factorized result agrees exactly with eq. (28) of Motyka et al.

One can also take the collinear limit, which as noted previously [49], can be obtained by taking $\mathbf{k}_{1\perp} \rightarrow 0$ and $\mathbf{k}_{2\perp} \rightarrow 0$ in the trace element, $\Theta(\mathbf{k}_{1\perp}, \mathbf{k}_{2\perp})/k_{1\perp}^2 k_{2\perp}^2$, but not

in the unintegrated functions. This means that the total external momenta vanishes, $\mathbf{p}_\perp + \mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} = 0$, thus guaranteeing momentum conservation. The limit

$$\lim_{\substack{\mathbf{k}_{1\perp} \rightarrow 0 \\ \mathbf{k}_{2\perp} \rightarrow 0}} \frac{\Theta(\mathbf{k}_{1\perp}, \mathbf{k}_{2\perp})}{\mathbf{k}_{1\perp}^2 \mathbf{k}_{2\perp}^2}, \quad (4.11)$$

is well defined thanks to the Ward identities

$$k_{1\nu_1} m_{ab}^{\mu\nu_1+}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = 0, \quad k_{2\nu_2} m_{ab}^{\mu-\nu_2}(k_1, k_2, \mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = 0, \quad (4.12)$$

ensuring that the amplitude vanishes linearly with $\mathbf{k}_{1\perp}$ and $\mathbf{k}_{2\perp}$.

The integration over $\mathbf{k}_{1\perp}(\mathbf{k}_{2\perp})$ has to be taken then only over the unintegrated distribution functions,

$$x_i f_{g,i}(x_i, Q^2) \equiv \frac{1}{4\pi^3} \int_0^{Q^2} d\mathbf{k}_\perp^2 \varphi_i(Y_i, \mathbf{k}_\perp) = \frac{1}{\pi^2} \int_{\mathbf{k}_\perp} \varphi_i(Y_i, \mathbf{k}_\perp), \quad i = p, A, \quad (4.13)$$

to get the inclusive photon cross section at fixed Q^2 and momentum fractions in the proton $x_p \sim \frac{Q_S^p}{\sqrt{s}} e^{\eta_{k_\gamma}}$ and in the nuclei $x_A \sim \frac{Q_S^A}{\sqrt{s}} e^{-\eta_{k_\gamma}}$, as

$$\frac{d\sigma^\gamma}{d^2\mathbf{k}_\perp d\eta_{k_\gamma}} = \frac{1}{16} \int_0^\infty \frac{dq^+}{q^+} \frac{dp^+}{p^+} \int_{\mathbf{q}_\perp \mathbf{p}_\perp} (2\pi)^2 \delta^{(2)}(\mathbf{p}_\perp + \mathbf{q}_\perp + \mathbf{k}_{\gamma\perp}) \times x_p f_{g,p}(x_p, Q^2) x_A f_{g,A}(x_A, Q^2) |\mathcal{M}_{gg \rightarrow q\bar{q}\gamma}|^2, \quad (4.14)$$

where the $|\mathcal{M}_{gg \rightarrow q\bar{q}\gamma}|^2$ object is defined as

$$|\mathcal{M}_{gg \rightarrow q\bar{q}\gamma}|^2 \equiv \lim_{\substack{\mathbf{k}_{1\perp} \rightarrow 0 \\ \mathbf{k}_{2\perp} \rightarrow 0}} \frac{q_f^2 \alpha_e \alpha_S^2}{N_c(N_c^2 - 1)} \frac{\Theta(\mathbf{k}_{1\perp}, \mathbf{k}_{2\perp})}{\mathbf{k}_{1\perp}^2 \mathbf{k}_{2\perp}^2}. \quad (4.15)$$

An especially interesting point to note here is the sensitivity of the collinear result in eq. (4.14) to the nuclear gluon distribution function $f_{g,A}$. The CGC formalism used in this paper naturally extends beyond this result to the multi-parton distributions of the saturated nucleus as the momentum scales probed approach the semi-hard saturation scale Q_S^A .

5 Summary and outlook

We have computed in this work the leading contribution to inclusive cross section for photon production at central rapidities in high energy proton-nucleus collisions. Our result for the triple differential cross section for a photon accompanied by a quark-antiquark pair is given in eq. (3.16) and that for the inclusive photon cross section is given in eq. (3.17). The result in this paper for the class III diagrams, in combination with the result for the class II diagrams in figure 2 obtained previously in [13], completes the NLO computation of inclusive photon production within the CGC framework.

The result in eq. (3.17) has an identical structure to the expression for quark-antiquark pair production computed previously in [16]. Moreover as we show explicitly in eq. (B.11) of appendix B, the Low-Burnett-Kroll theorem tells us that, in the soft photon limit, the amplitude for photon production is precisely the amplitude for quark-antiquark pair production multiplied by a simple kinematic expression with the Lorentz structure of the photon.

The properties of the heavy quark pair production cross section derived in [16] have been explored extensively [36, 37]. These results, when combined with a CGC+non-relativistic QCD (NRQCD) formalism [50], provide an excellent description of p+p J/Ψ production data [51] and p+A J/Ψ production data [52] at both RHIC and the LHC. The same formalism has also been employed to study J/Ψ production in p+A collisions within a color evaporation model of the hadronization of charm-anticharm pairs to J/Ψ mesons [53, 54].

Computational techniques identical to those employed in these works can be used for quantitative estimates of inclusive photon production in p+A collisions at RHIC and LHC. The momentum dependent multi-parton correlations functions $\phi_A^{g,g}$, $\phi_A^{q\bar{q},g}$ and $\phi_A^{q\bar{q},q\bar{q}}$ appearing in eq. (3.17) can be computed within the non-local Gaussian approximation we alluded to previously; this approximation reproduces a Langevin numerical implementation of the JIMWLK hierarchy [44] that delivers closed form results for such multi-parton correlators. The large N_c limit of the multi-parton correlators provides an added simplification. Thus while the number of integrals to be performed are greater in the photon case relative to that of $q\bar{q}$ production, the computation of the former is feasible and will be reported on in future.

The numerical results will be very relevant for comparisons to anticipated results for direct photon measurements in p+A collisions at RHIC and the LHC. As noted, such measurements will be very sensitive to the nuclear gluon distribution function and will provide a quantitative estimate of power corrections to the same. Currently, the deuteron-gold measurements [46, 47] at RHIC have covered the kinematic range $1 \text{ GeV} \lesssim k_{\gamma\perp} \lesssim 6 \text{ GeV}$ with nearly real virtual photons and $5 \text{ GeV} \lesssim k_{\gamma\perp} \lesssim 16 \text{ GeV}$ with real photons. It will be important to extend the latter measurements to lower k_{\perp} to fully explore the gluon saturation regime. While the data is in agreement with pQCD, the remaining uncertainty allows for the possibility of thermal photons [55] on top of the pQCD results. Computations in our framework will help determine whether the latter are necessary.

Further, prompt photon measurements will provide an important test of the gluon saturation in general and, in particular, of the multi-parton correlators we have discussed here. They should corroborate the above mentioned studies of quarkonium production and may potentially be more robust since they are less sensitive to hadronization effects. We also note that our framework may provide insight into a long standing experimental puzzle [56] regarding the “anomalously” large photon production at soft momenta relative to predictions based on the Low-Burnett-Kroll theorem. We will investigate these issues in future work.

Another interesting feature of the results presented here is the comparative study of photon production in Lorentz gauge and light-cone gauge. While this study is a useful check of our results, it may also have further value in higher order computations that are feasible in this framework.

A Photon amplitude in light-cone gauge

A.1 Derivation of the amplitude

The treatment of the quantum fluctuations would be easier in the light-cone gauge, $A^+ = 0$, while the classical solution of the Yang-Mills equation would be more complicated in the light-cone gauge having transverse components than in the Lorenz gauge. Interestingly, the non-zero component of the classical solution obtained in the Lorenz gauge is A^- only and $A^+ = 0$ is consistent with the light-cone gauge. Here, we adopt such a hybrid choice of gauge fixing with the background field in the Lorenz gauge and the quantum fluctuations in the light-cone gauge [20, 57]. Then, unlike the Lorenz gauge, the gauge field from the proton color source does not depend on $V(\mathbf{x}_\perp)$ but only $U(\mathbf{x}_\perp)$. We can write it as

$$A_{\text{LC}}^\mu(q) = A_{p,\text{LC}}^\mu(q) + \frac{ig}{q^2 + iq^+\epsilon} \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} e^{i(\mathbf{q}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} C^\mu(q, \mathbf{k}_{1\perp}) U(\mathbf{x}_\perp) \frac{\rho_p(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2}, \quad (\text{A.1})$$

where the first term represents,

$$A_{p,\text{LC}}^\pm(q) = 0, \quad \mathbf{A}_{p,\text{LC}\perp}(q) = \frac{ig \mathbf{q}_\perp}{(q^+ + i\epsilon)(q^- - i\epsilon)} \frac{\rho_p(\mathbf{q}_\perp)}{\mathbf{q}_\perp^2}. \quad (\text{A.2})$$

We note that $A_{p,\text{LC}}$ is non-zero only in the $x^+ < 0$ region thanks to the pole at $q^- = i\epsilon$, while the second term in eq. (A.1) is non-zero only in the $x^+ > 0$ region. The components of $C^\mu(q, \mathbf{k}_{1\perp})$ in the light-cone gauge are

$$\begin{aligned} C^+(q, \mathbf{k}_{1\perp}) &= 0, & C^-(q, \mathbf{k}_{1\perp}) &= \frac{-2\mathbf{k}_{1\perp} \cdot (\mathbf{q}_\perp - \mathbf{k}_{1\perp})}{q^+ + i\epsilon}, \\ \mathbf{C}_\perp(q; \mathbf{k}_{1\perp}) &= \frac{\mathbf{q}_\perp \mathbf{k}_{1\perp}^2}{(q^+ + i\epsilon)(q^- + i\epsilon)} - 2\mathbf{k}_{1\perp}. \end{aligned} \quad (\text{A.3})$$

Because no $V(\mathbf{x}_\perp)$ appears, we do not have to consider the singular diagrams.

We can give the counterparts of the amplitude vectors corresponding to the diagrams (R1)–(R2) in figure 3 as

$$\mathcal{M}_1^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = \bar{u}(\mathbf{q})(-iq_f e\gamma^\mu)S_0(q+k_\gamma)(-igA_{\text{LC}}(P) \cdot t)v(\mathbf{p}), \quad (\text{A.4})$$

$$\mathcal{M}_2^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = \bar{u}(\mathbf{q})(-igA_{\text{LC}}(P) \cdot t)S_0(-p-k_\gamma)(-iq_f e\gamma^\mu)v(\mathbf{p}), \quad (\text{A.5})$$

This expression seems to be parametrically identical to that in the Lorenz gauge but a difference arises from the gauge field from the proton; in the Lorenz gauge A_R^μ appear with C_U^μ and C_V^μ or C_L^μ after cancellation of C_V^μ , while in the light-cone gauge A_{LC}^μ appear with C^μ as defined above. After some calculations we find,

$$\begin{aligned} \mathcal{M}_\beta^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) & \quad (\text{A.6}) \\ &= -q_f e g^2 \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} [U(\mathbf{x}_\perp) - 1]^{ba} \bar{u}(\mathbf{q}) R_\beta^{\mu\nu} C_\nu(P, \mathbf{k}_{1\perp}) t^b v(\mathbf{p}), \end{aligned}$$

where $\beta = 1, 2$. To facilitate a comparison between different gauges we introduced extended tensors for Dirac indices as

$$R_1^{\mu\nu} \equiv -\frac{1}{P^2} \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^\nu, \quad R_2^{\mu\nu} \equiv \frac{1}{P^2} \gamma^\nu \frac{\not{p} + \not{k}_\gamma - m}{(p+k_\gamma)^2 - m^2} \gamma^\mu, \quad (\text{A.7})$$

and for later convenience we also define

$$R_g^{\mu\nu} \equiv \sum_{\beta=1}^2 R_\beta^{\mu\nu}. \quad (\text{A.8})$$

Now we understand that we can express $T_g^\mu(\mathbf{k}_{1\perp})$ in the Lorenz gauge as

$$T_g^\mu(\mathbf{k}_{1\perp}) = R_g^{\mu\nu} C_{L\nu}(P, \mathbf{k}_{1\perp}). \quad (\text{A.9})$$

Similarly, we proceed to evaluate the counterparts of regular diagrams (3)–(8) in figure 4. For example, let us look carefully at the evaluation of \mathcal{M}_3^μ . The diagram (3) immediately leads to

$$\begin{aligned} \mathcal{M}_3^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) & \quad (\text{A.10}) \\ &= \int \frac{d^4 k_2}{(2\pi)^4} \bar{u}(\mathbf{q})(-iq_f e\gamma^\mu)S_0(q+k_\gamma)\mathcal{T}(q+k_\gamma, k_2)S_0(q+k_\gamma-k_2)(-igA_{\text{LC}}(P-k_2) \cdot t)v(\mathbf{p}). \end{aligned}$$

in which only $A_{p,\text{LC}}^\mu$ contributes. In the above expression the k_2^+ integration is trivial once we insert the effective vertex $\mathcal{T}(q+k_\gamma, k_2)$, given in (2.11). The k_2^- integration picks up a singularity in $S_0(q+k_\gamma-k_2)$. After the variable change $k_2 = P - k_1$ we find

$$\mathcal{M}_3^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = q_f e g^2 \int_{\mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i(\mathbf{P}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{x}_\perp} \bar{u}(\mathbf{q}) R_3^{\mu i}(\mathbf{k}_{1\perp}) \frac{k_{1i}}{P^+} [\tilde{U}(\mathbf{x}_\perp) - 1] t^a v(\mathbf{p}), \quad (\text{A.11})$$

where

$$R_3^{\mu\nu}(\mathbf{k}_{1\perp}) \equiv \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^+ \frac{\not{k}_1 - \not{p} + m}{2(q^+ + k_\gamma^+)p^- + M^2(\mathbf{k}_{1\perp} - \mathbf{p}_\perp)} \gamma^\nu. \quad (\text{A.12})$$

We note that in the Lorenz gauge $R_3^{\mu i}(\mathbf{k}_{1\perp})(k_{1i}/P^+)$ would be replaced with $-R_3^{\mu -}$. For diagrams (4)–(8) we can carry out similar procedures to define $R_\beta^{\mu\nu}(\mathbf{k}_{1\perp})$ by generalizing γ^- in $R_\beta^\mu(\mathbf{k}_{1\perp})$ to γ^ν , and then \mathcal{M}_β^μ is simply given by $R_\beta^{\mu i}(\mathbf{k}_{1\perp})(k_{1i}/P^+)$ instead of $-R_\beta^{\mu -}(\mathbf{k}_{1\perp})$. By analogy to eq. (2.26) we define

$$R_q^{\mu\nu}(\mathbf{k}_{1\perp}) \equiv \sum_{\beta=3}^5 R_\beta^{\mu\nu}(\mathbf{k}_{1\perp}), \quad R_{\bar{q}}^{\mu\nu}(\mathbf{k}_{1\perp}) \equiv \sum_{\beta=6}^8 R_\beta^{\mu\nu}(\mathbf{k}_{1\perp}), \quad (\text{A.13})$$

where $T_q^\mu(\mathbf{k}_{1\perp})$ and $T_{\bar{q}}^\mu(\mathbf{k}_{1\perp})$ can be obtained as $T_q^\mu(\mathbf{k}_{1\perp}) = R_q^{\mu -}(\mathbf{k}_{1\perp})$ and $T_{\bar{q}}^\mu(\mathbf{k}_{1\perp}) = R_{\bar{q}}^{\mu -}(\mathbf{k}_{1\perp})$.

Let us turn to contributions from diagrams (9)–(12) in figure 5. Here, we look specifically at the diagram (9) that yields,

$$\begin{aligned} \mathcal{M}_9^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= \int \frac{d^4 k}{(2\pi)^4} \frac{d^4 k_1}{(2\pi)^4} \bar{u}(\mathbf{q})(-iq_f e \gamma^\mu) S_0(q+k_\gamma) \mathcal{T}(k, q+k_\gamma) S_0(q+k_\gamma-k) \\ &\quad \times (-ig A_{\text{LC}}(k_1) \cdot t) S_0(q+k_\gamma-k-k_1) \mathcal{T}(P-k-k_1, q+k_\gamma-k-k_1) v(\mathbf{p}). \end{aligned} \quad (\text{A.14})$$

The integrations over k^+ and k_1^+ are trivial thanks to the nuclear effective vertex \mathcal{T} . For the integrations over k^- and k_1^- we pick up the singularities in the quark propagators $S_0(q+k_\gamma-k)$ and in $S_0(q+k_\gamma-k-k_1)$. We find

$$\begin{aligned} \mathcal{M}_9^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) &= q_f e g^2 \int_{\mathbf{k}_\perp \mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp \mathbf{y}_\perp} \frac{\rho_p^a(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp} \\ &\quad \times \bar{u}(\mathbf{q}) R_9^{\mu i}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \frac{k_{1i}}{P^+} [\tilde{U}(\mathbf{x}_\perp) - 1] t^a [\tilde{U}^\dagger(\mathbf{y}_\perp) - 1] v(\mathbf{p}), \end{aligned} \quad (\text{A.15})$$

where

$$R_9^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) = \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^+ (\not{q} + \not{k}_\gamma - \not{k}_1 + m) \gamma^\nu \frac{(\not{q} + \not{k}_\gamma - \not{k} - \not{k}_1 + m) \gamma^+}{N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp})}. \quad (\text{A.16})$$

A similar calculation can be performed for the remaining diagrams (10)–(12). For $\beta = 9, \dots, 12$, the difference from the Lorenz gauge calculation is to again have the replacement $R_\beta^{\mu i}(k_{1i}/P^+)$ instead of $-R_\beta^{\mu -}$. By analogy to eq. (2.29) we define

$$R_{q\bar{q}}^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv \sum_{\beta=9}^{12} R_\beta^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}). \quad (\text{A.17})$$

Obviously, we can express $T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ through $R_{q\bar{q}}^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ as

$$T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) = R_{q\bar{q}}^{\mu -}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}). \quad (\text{A.18})$$

Finally, below we list the singularities we picked up when calculating the integrations over k_1^- in the amplitudes with $\beta = 9, \dots, 12$

$$\begin{aligned} k_{1(9)}^- &= \frac{M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp)}{2(q^+ + k_\gamma^+)} + \frac{M^2(\mathbf{q}_\perp + \mathbf{k}_{\gamma\perp} - \mathbf{k}_\perp - \mathbf{k}_{1\perp})}{2p^+} - i\varepsilon, \\ k_{1(10)}^- &= \frac{M^2(\mathbf{q}_\perp - \mathbf{k}_\perp)}{2q^+} + \frac{M^2(\mathbf{q}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp})}{2(p^+ + k_\gamma^+)} - i\varepsilon, \\ k_{1(11)}^- &= i\varepsilon, \quad k_{1(12)}^- = i\varepsilon. \end{aligned} \quad (\text{A.19})$$

By using the relations

$$R_g^{\mu\nu} C_\nu(P, \mathbf{P}_\perp) + \left[R_q^{\mu i}(\mathbf{P}_\perp) + R_{\bar{q}}^{\mu i}(\mathbf{P}_\perp) - R_{q\bar{q}}^{\mu i}(\mathbf{0}, \mathbf{P}_\perp) \right] \frac{P_i}{P^+} = 0, \quad (\text{A.20})$$

$$R_q^{\mu i}(\mathbf{P}_\perp - \mathbf{k}_\perp) - R_{q\bar{q}}^{\mu\nu}(\mathbf{k}_\perp, \mathbf{P}_\perp - \mathbf{k}_\perp) = 0, \quad R_{\bar{q}}^{\mu\nu}(\mathbf{k}_{1\perp}) - R_{q\bar{q}}^{\mu\nu}(\mathbf{0}, \mathbf{k}_{1\perp}) = 0,$$

we find that the terms in the amplitude that do not contain a Wilson line or contain only one Wilson line cancel. Eqs. (A.20) are analogous to eqs. (2.46). Now, the complete expression for the amplitude is thus,

$$\mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = -q_f e g^2 \int_{\mathbf{k}_\perp \mathbf{k}_{1\perp}} \int_{\mathbf{x}_\perp \mathbf{y}_\perp} \frac{\rho_p^\alpha(\mathbf{k}_{1\perp})}{\mathbf{k}_{1\perp}^2} e^{i\mathbf{k}_\perp \cdot \mathbf{x}_\perp + i(\mathbf{P}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp}) \cdot \mathbf{y}_\perp} \quad (\text{A.21})$$

$$\times \bar{u}(\mathbf{q}) \left\{ R_g^{\mu\nu} C_\nu(P, \mathbf{k}_{1\perp}) U^{ba}(\mathbf{x}_\perp) t^b - R_{q\bar{q}}^{\mu i}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \frac{k_{1i}}{P^+} \tilde{U}(\mathbf{x}_\perp) t^a \tilde{U}^\dagger(\mathbf{y}_\perp) \right\} v(\mathbf{p}).$$

A.2 Equivalence with the amplitude in the Lorenz gauge

There are two apparent differences between the light-cone gauge amplitude in eq. (A.21) and the Lorenz gauge amplitude in eq. (2.47); first, $C^\nu(P, \mathbf{k}_{1\perp})$ is replaced with the Lipatov vertex $C_L^\nu(P, \mathbf{k}_{1\perp})$, and second, the gluon vertex in the quantity $T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ carries a light-cone index instead of the transverse index, as seen in eq. (A.21). We can show that they are identical by two-step arguments. First, let us look at the difference between C^ν and C_L^ν , that is,

$$C^\nu(P, \mathbf{k}_{1\perp}) - C_L^\nu(P, \mathbf{k}_{1\perp}) = \left(\frac{\mathbf{k}_{1\perp}^2}{P^+ P^-} - 1 \right) P^\nu + \frac{P^2}{P^+} \delta^{\nu+}. \quad (\text{A.22})$$

We contract this difference with $R_g^{\mu\nu}$ and sandwich it with the $\bar{u}(\mathbf{q})$ and $v(\mathbf{p})$ spinors. We find

$$\begin{aligned} & \bar{u}(\mathbf{q}) R_g^{\mu\nu} [C_{L\nu}(P, \mathbf{k}_{1\perp}) - C_\nu(P, \mathbf{k}_{1\perp})] v(\mathbf{p}) \\ &= \bar{u}(\mathbf{q}) \left[R_g^{\mu\nu} C_{L\nu}(P, \mathbf{k}_{1\perp}) - T_g^\mu(\mathbf{k}_{1\perp}) \right] v(\mathbf{p}) \quad (\text{A.23}) \\ &= -\frac{1}{P^+} \bar{u}(\mathbf{q}) \left[\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \gamma^+ - \gamma^+ \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu \right] v(\mathbf{p}). \end{aligned}$$

In the first line we used (A.9) and in the second line we used the Dirac equation.

Next, we work on the part of the amplitude containing $R_{q\bar{q}}^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$. With some calculations we can prove that for $\beta = 9, \dots, 12$,

$$\sum_{\beta=9}^{12} \bar{u}(\mathbf{q}) R_\beta^{\mu\nu}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \tilde{k}_{1(\beta)\nu} v(\mathbf{p}) = 0, \quad (\text{A.24})$$

where the four vector $\tilde{k}_{1(\beta)}$ is defined with $\tilde{k}_{1(\beta)}^+ = P^+$ and $\tilde{k}_{1(\beta)}^-$ from the singularity of the integrand, see eqs. (A.19), as well as $\tilde{\mathbf{k}}_{1(\beta)\perp} = \mathbf{k}_{1\perp}$.

For $R_{11,12}^{\mu\nu}$ the singularity is located at $k_{1(11)}^- = k_{1(12)}^- = 0$, see eq. (A.19), and so from eq. (A.24) we have,

$$\begin{aligned} & \bar{u}(\mathbf{q}) [T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) P^+ + R_{q\bar{q}}^{\mu i}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) k_{1i}] v(\mathbf{p}) \quad (\text{A.25}) \\ &= -\bar{u}(\mathbf{q}) R_{q\bar{q}}^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) k_{1(\beta)}^- v(\mathbf{p}) = -\bar{u}(\mathbf{q}) [R_9^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) k_{1(9)}^- + R_{10}^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) k_{1(10)}^-] v(\mathbf{p}), \end{aligned}$$

where in the first line we used eq. (A.18). We consider the first term for the moment and use the explicit expression for $R_9^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ from eq. (A.16) as well as the explicit form of $k_{1(9)}^-$, see eq. (A.19). We then find,

$$\begin{aligned} & \bar{u}(\mathbf{q})R_9^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp})k_{1(9)}^-v(\mathbf{p}) \\ &= \bar{u}(\mathbf{q})\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^+ \frac{(\not{q} + \not{k}_\gamma - \not{k} + m)\gamma^+(\not{q} + \not{k}_\gamma - \not{k} - \not{k}_1 + m)v(\mathbf{p})}{-2p^+ 2(q^+ + k_\gamma^+)} \\ &= -\bar{u}(\mathbf{q})\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^+ v(\mathbf{p}). \end{aligned} \tag{A.26}$$

In the second line we moved γ^+ and used $(\gamma^+)^2 = 0$. The second term, containing $R_{10}^{\mu+}(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$, can be manipulated in a similar way, leading to

$$\begin{aligned} & \bar{u}(\mathbf{q}) \left[T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) + R_{q\bar{q}}^{\mu i}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \frac{k_{1i}}{P^+} \right] v(\mathbf{p}) \\ &= \frac{1}{P^+} \bar{u}(\mathbf{q}) \left[\gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q+k_\gamma)^2 - m^2} \gamma^+ - \gamma^+ \frac{\not{p} + \not{k}_\gamma - m}{(p+k_\gamma)^2 - m^2} \gamma^\mu \right] v(\mathbf{p}). \end{aligned} \tag{A.27}$$

This has exactly the same form as eq. (A.23) but with an opposite sign. To end the proof we note that eq. (A.27) is independent of \mathbf{k}_\perp and so we effectively have $\mathbf{x}_\perp = \mathbf{y}_\perp$ in the fundamental Wilson lines in the amplitude (A.21). Then we can use the following identity,

$$\tilde{U}(\mathbf{x}_\perp)t^a\tilde{U}^\dagger(\mathbf{x}_\perp) = t^bU^{ba}(\mathbf{x}_\perp), \tag{A.28}$$

which will ensure that eqs. (A.23) and (A.27) cancel out once these expressions are multiplied by the appropriate Wilson lines.

B Properties of the photon production amplitude

In this appendix we will prove that the amplitude satisfies the photon Ward identity and the famous Low-Burnett-Kroll soft photon theorem [21–23]. The Low-Burnett-Kroll theorem states that, in the infrared limit for the radiated photon momentum, i. e. $k_\gamma \rightarrow 0$, the amplitude should factorize into the product of the non-radiative amplitude, the photon polarization vector, and a vectorial structure that depends on momenta of the emitted charged particles.

We will rely on diagrammatic representations in the derivation in section 2 though our conclusions will be valid of course for another derivation in A.

B.1 Photon Ward identity

The photon Ward identity implies that the amplitude vector given in eq. (2.47) should satisfy

$$k_{\gamma\mu}\mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) = 0. \tag{B.1}$$

As we demonstrate below, this is satisfied independently for T_g^μ and $T_{q\bar{q}}^\mu$ terms that constitute the total amplitude. For T_g^μ , we immediately notice,

$$\bar{u}(\mathbf{q}) k_{\gamma\mu} T_g^\mu(\mathbf{k}_{1\perp}) v(\mathbf{p}) = \frac{1}{P^2} \bar{u}(\mathbf{q}) \left[\not{C}_L(P, \mathbf{k}_{1\perp}) \frac{\not{p} - m}{2p \cdot k_\gamma} \not{k}_\gamma - \not{k}_\gamma \frac{\not{q} + m}{2q \cdot k_\gamma} \not{C}_L(P, \mathbf{k}_{1\perp}) \right] v(\mathbf{p}) = 0, \quad (\text{B.2})$$

which we can easily prove using $(\not{p} - m)\not{k}_\gamma = -\not{k}_\gamma(\not{p} - m) + 2p \cdot k_\gamma$ in the first term and $\not{k}_\gamma(\not{q} + m) = -(\not{q} + m)\not{k}_\gamma + 2q \cdot k_\gamma$ in the second term and the Dirac equations satisfied by $\bar{u}(\mathbf{q})$ and $v(\mathbf{p})$. For $T_{q\bar{q}}^\mu$, it is somewhat more involved to prove a counterpart of the identity. By definition as given in eq. (2.29) $T_{q\bar{q}}^\mu$ is a sum of R_β^μ with $\beta = 9, \dots, 12$. Using the explicit forms of R_β^μ in eq. (2.30), we can prove the following relation,

$$\bar{u}(\mathbf{q}) k_{\gamma\mu} [R_9^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) + R_{11}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp})] v(\mathbf{p}) = -\bar{u}(\mathbf{q}) k_{\gamma\mu} [R_{10}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) + R_{12}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp})] v(\mathbf{p}).$$

The different denominators in the expressions above, $N_k(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ in R_9^μ and R_{11}^μ and $N_q(\mathbf{k}_\perp, \mathbf{k}_{1\perp})$ in R_{10}^μ and R_{12}^μ , cancel with the numerator after taking the contraction with the photon momentum, $k_{\gamma\mu}$. This cancellation occurs in a way similar to the T_g^μ case as a consequence of anticommuting the gamma matrices and using the Dirac equations satisfied by $\bar{u}(\mathbf{q})$ and $v(\mathbf{p})$ as well as using the on-shell-ness of the photon momentum. This leads to

$$\bar{u}(\mathbf{q}) k_{\gamma\mu} T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) v(\mathbf{p}) = 0. \quad (\text{B.3})$$

Since the T_g^μ and the $T_{q\bar{q}}^\mu$ contributions separately vanish, we have confirmed that the photon Ward identity (B.1) is certainly satisfied.

B.2 Soft-photon factorization

As we will demonstrate explicitly, the photon production amplitude we have derived satisfies the Low-Burnett-Kroll theorem: we will recover the non-radiative amplitude (and sub-leading pieces coming from the diagrams (11) and (12) in figure 5 in which the photon is not radiated from external legs) The leading contributions encompass sub-processes in which the photon is radiated after the $q\bar{q}$ pair scatters off the nucleus, and thus the photon is attached to external legs. Such leading terms possess the factor,

$$\frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \quad \text{or} \quad \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2}. \quad (\text{B.4})$$

The numerators are finite in the $k_\gamma \rightarrow 0$ limit, and non-vanishing contributions under this limit are

$$\begin{aligned} \gamma^\mu(\not{p} + \not{k}_\gamma - m)v(\mathbf{p}) &\rightarrow (\not{p} - m)\gamma^\mu v(\mathbf{p}) = 2p^\mu v(\mathbf{p}), \\ \bar{u}(\mathbf{q})\gamma^\mu(\not{q} + \not{k}_\gamma + m) &\rightarrow \bar{u}(\mathbf{q})\gamma^\mu(\not{q} + m) = 2q^\mu \bar{u}(\mathbf{q}), \end{aligned} \quad (\text{B.5})$$

while the denominators are linearly divergent in the $k_\gamma \rightarrow 0$

$$(p + k_\gamma)^2 - m^2 \rightarrow 2p \cdot k_\gamma, \quad (q + k_\gamma)^2 - m^2 \rightarrow 2q \cdot k_\gamma. \quad (\text{B.6})$$

With these simplifications, we find,

$$\begin{aligned}
& \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) T_g^\mu(\mathbf{k}_{1\perp}) \\
&= \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \frac{1}{P^2} \left[\not{C}_L(P, \mathbf{k}_{1\perp}) \frac{\not{p} + \not{k}_\gamma - m}{(p + k_\gamma)^2 - m^2} \gamma^\mu - \gamma^\mu \frac{\not{q} + \not{k}_\gamma + m}{(q + k_\gamma)^2 - m^2} \not{C}_L(P, \mathbf{k}_{1\perp}) \right] \\
&\rightarrow \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \left(\frac{p^\mu}{p \cdot k_\gamma} - \frac{q^\mu}{q \cdot k_\gamma} \right) T_g(\mathbf{k}_{1\perp}), \tag{B.7}
\end{aligned}$$

where the last piece defined by

$$T_g(\mathbf{k}_{1\perp}) \equiv \frac{\not{C}_L(p + q, \mathbf{k}_{1\perp})}{(p + q)^2}, \tag{B.8}$$

is the expression obtained in the computation of the amplitude for quark-antiquark pair production [16].

For $T_{q\bar{q}}^\mu$, at the leading order, we only have to concern ourselves with diagrams (9) and (10) in figure 5. This is because the contributions from (11) and (12) do not contain any quark propagator in the form of eq. (B.4), while (9) and (10) are divergent in the $k_\gamma \rightarrow 0$ limit, and this explains our identification of (9) and (10) as leading contributions and (11) and (12) as sub-leading ones. From this argument we can show that the $T_{q\bar{q}}^\mu$ term with leading contributions only behaves as follows,

$$\epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) T_{q\bar{q}}^\mu(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \rightarrow \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \left(\frac{p^\mu}{p \cdot k_\gamma} - \frac{q^\mu}{q \cdot k_\gamma} \right) T_{q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}), \tag{B.9}$$

where the last piece defined by

$$T_{q\bar{q}}(\mathbf{k}_\perp, \mathbf{k}_{1\perp}) \equiv \frac{\gamma^+(\not{q}_\perp - \not{k}_\perp + m) \gamma^-(\not{q}_\perp - \not{k}_\perp - \not{k}_{1\perp} + m) \gamma^+}{2p^+ M^2(\mathbf{q}_\perp - \mathbf{k}_\perp) + 2q^+ M^2(\mathbf{q}_\perp - \mathbf{k}_\perp - \mathbf{k}_{1\perp})}, \tag{B.10}$$

is the expression that also appears as a part of the amplitude for quark-antiquark pair production [16]. It should be noted that in the computation in ref. [16] only the leading terms have been concerned, while the $k_\gamma \rightarrow 0$ limit of the amplitude in the present work can also pick up the sub-leading rest from diagrams (11) and (12). Combining both sets of leading contributions in the soft photon limit, we then get,

$$\epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \mathcal{M}^\mu(\mathbf{p}, \mathbf{q}, \mathbf{k}_\gamma) \rightarrow -q_f e \epsilon_\mu^*(\mathbf{k}_\gamma, \lambda) \left(\frac{p^\mu}{p \cdot k_\gamma} - \frac{q^\mu}{q \cdot k_\gamma} \right) \mathcal{M}(\mathbf{q}, \mathbf{p}), \tag{B.11}$$

where $\mathcal{M}(\mathbf{q}, \mathbf{p})$ is the amplitude for $q\bar{q}$ pair production found in ref. [16], and eq. (B.11) verifies that the Low-Burnett-Kroll theorem in the $k_\gamma \rightarrow 0$ limit is satisfied.
